1 Introduction

This report documents the update and validation of the Gainesville Urbanized Area Transportation Study 2010 base year travel demand model conducted as integral part of the Gainesville Urbanized Area Year 2040 Long Range Transportation Plan update. The 2010 model study area covers all of Alachua County, including the nine municipalities within the county (cities of Alachua, Archer, Gainesville, Hawthorne, High Springs, Newberry, Waldo and towns of La Crosse and Micanopy). The effort involved updating the input files of the previous 2007 model to 2010 and reviewing and enhancing the model parameters and scripts for trip generation, distribution, highway and transit network development, mode choice, assignment and reporting steps. The Florida Department of Transportation's *FSUTMS-Cube Framework Phase II: Model Calibration and Validation Standards* was followed as a technical guide for the validation effort.

The structure of the report generally follows the sequence of the processes in the model chain. It starts with documenting the update of the external trips in Section 2. Sections 3 and 4 cover trip generation and trip distribution. Section 5 documents transit accessibility and path building followed by mode choice in Section 6. Sections 7 and 8 document highway and transit assignments. Finally, Section 9 concludes the report with closing remarks.

2 External Trips

The external zones are placed along roadways entering and leaving the Gainesville Urbanized Area Transportation Study model region. The zones used in the 2010 base model are based on the 2007 model. There are 26 external zones outside of study area, and they are assigned unique Traffic Analysis Zone numbers from 600 to 625.

2.1 Internal-External and External-External Trips

External trips are vehicle trips having at least one trip end outside of the model study area. External trips include two categories: External-to-External trips and Internal-to-External trips or External-to-Internal trips. External-External trips are trips with both ends outside the study area, and trips with one end inside and one end outside the study area are called either Internal-External trips or External-Internal trips depending on the origin and destination.

External trips are generated or attracted at the external stations located outside of the model boundary. As described above, these stations are points of entry or exit of the study area. The external stations for the Gainesville Urbanized Area Transportation Study regional travel demand model are shown in Figure 2.1.

In the validation process of external trips, the External-External and External-Internal should ideally be estimated based on an external station origin-destination travel survey. In the absence of a recent origin-destination travel survey, the base year 2010 External-External and External-Internal trips were derived from the 2007 External-External and External-Internal trips factored by the 2010 traffic counts obtained from Florida Department of Transportation and Alachua County. There are two input files that influence external trips. These are the INTEXT and EETRIPS files with scenario year at the end of each file name. The percent of External-External and External-Internal trips were calculated from the 2007 model. However, because the external trips are derived from traffics counts without an origin-destination travel survey, it is necessary to make adjustments based on logic and local knowledge. These adjustments were conducted in an iterative manner in order to ensure that generated traffic volumes correspond to the 2010 traffic counts.

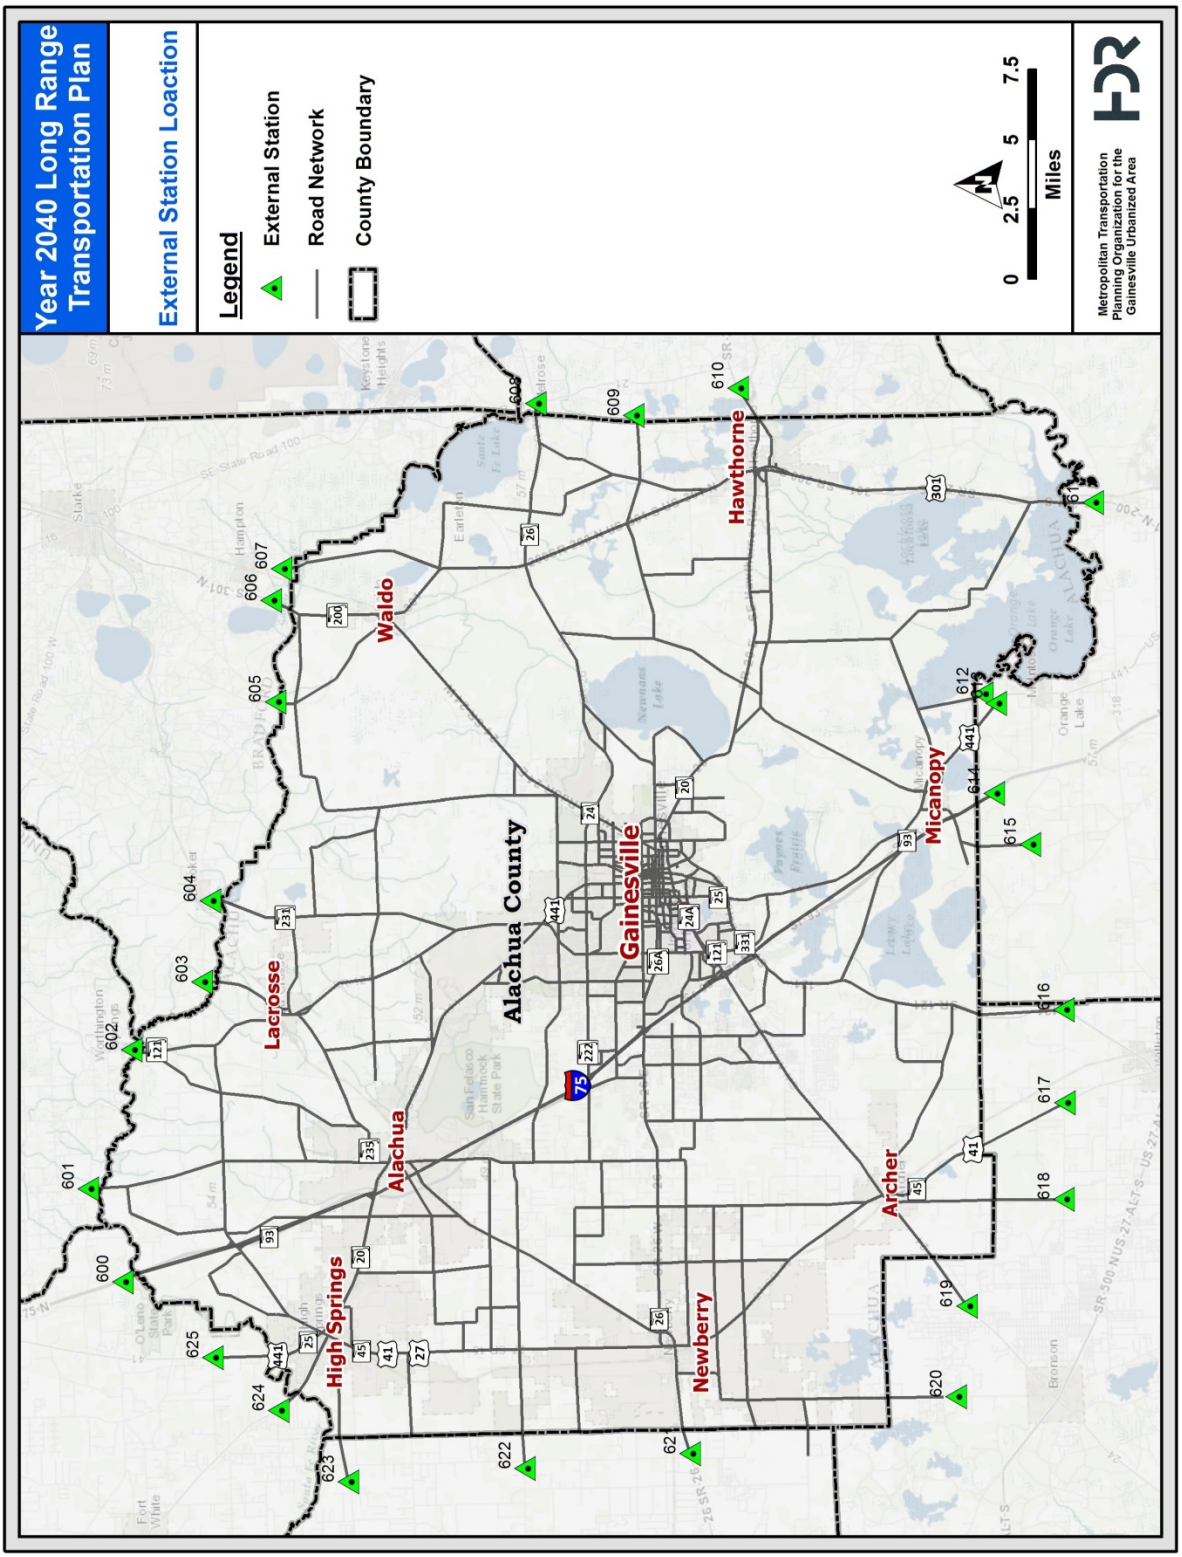

Figure 2.1 External Station Locations

The final 2010 External-External and External-Internal trips are shown in Table 2.1. Since the traffic patterns in Florida are heavily impacted by seasonality, the annual average daily traffic (AADT) is converted to peak-season weekday average daily traffic (PSWADT) through a model output conversion factor (MOCF) before coding into the model. The percentage of External-External and External-Internal are applied to the peak-season weekday average daily traffic for each external zone to calculate total External-External and External-Internal trips.

Table 2.1 Internal-External and External-External Percentage Splits

External Traffic Analysis Zone	Total External Trips	Road Way	Total IE Trips	Total EE Trips	IE %	EE %
600	47,368	*I-75 (North) at Columbia County Line*	11,290	36,078	24%	76%

625	6,062	US 441 *(Northwest) at Columbia County Line*	4,262	1,800	70%	30%

2.2 External Validation Adjustments

In the absence of a travel survey, several iterations of adjustments were conducted to achieve a goal of 1.0 volume-over-count ratio at each external station. For external zones 601, 603, 605, 607, 609, 615, 618, 622 and 623, 2010 annual average daily traffic was not available. Traffic count data from 2007 and 2011 were used to interpolate counts for 2010. For external station 612, which is located on a minor collector road, the count used in the 2007 model was utilized due to the absence of any nearby count station. Traffic counts at adjacent links were used with appropriate adjustments for the external zone 610.

An Iterative Proportional Fitting (IPF) process was used by creating a seed distribution and iteratively adjusting the cell values until a good match between the target row and column totals was achieved. For External-External trip tables, the row and column total targets represent the portions of the external station productions and attractions. For the External-Internal and Internal-External trips, productions and attractions are generated for both ends of the trip, the internal end of the trip and the external end of the trip. The traffic counts acted as control total at each external zone such that the total number of vehicle trips (Internal-External, External-Internal, and External-External) generated at an external station is equal to the traffic count at the external station.

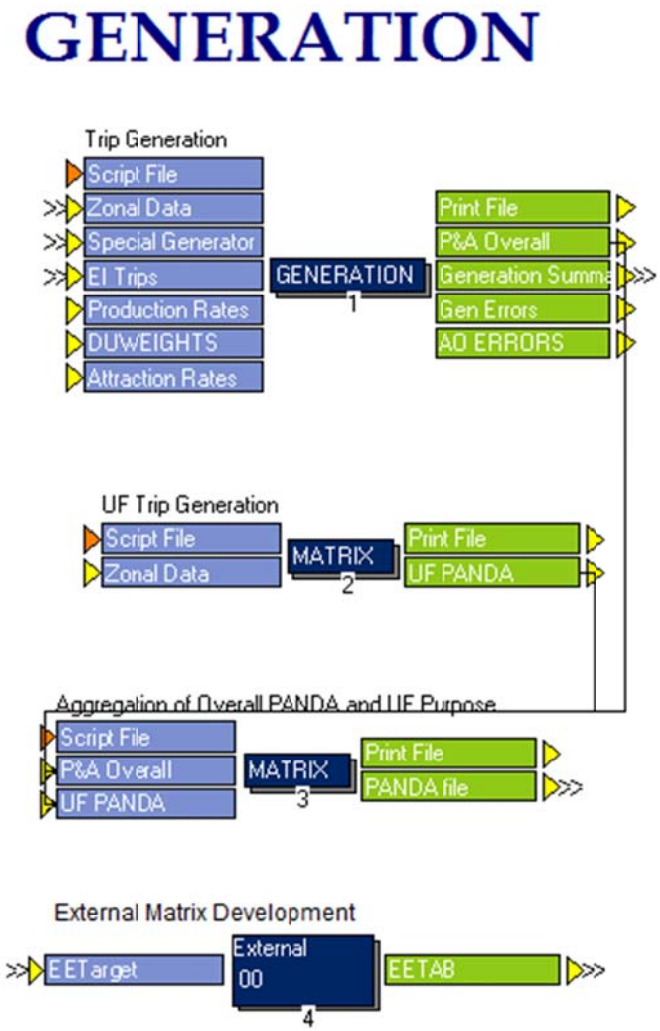
2.3 External Validation Results

The final model validation results will be discussed in the highway assignment section. The assignment results indicate reasonable match between the external travel movements estimated by the model and the traffic counts. The external cordon line achieves a volume-over-count ratio of 1.00. Corridors leading to or nearby external zones also were validated to satisfactory levels, based on this iterative adjustment process.

3 Trip Generation

Trip Generation is the first step of the four-step travel demand forecasting process. In this step, the amount of travel by trip purposes are calculated. Trip generation focuses on the locations generating the travel, and not the directionality of travel. Trip generation models provide the estimates of the number of trips by purpose produced by (trip production) or attracted to (trip attraction) a traffic analysis zone as a function of the demographic, socioeconomic, and land use characteristics of the zone. The most common forms of trip production and attraction models are cross-classification and linear regression. Cross-classification is generally used for trip production models and regression is used for trip attraction models. Figure 3.1 shows the trip generation model chain.

Figure 3.1 Trip Generation Model Chain



3.1 Trip Generation Process

The Alachua County 2010 model uses cross classification trip production rates stratified by auto availability (0, 1, 2, and 3+ auto Households), dwelling unit type (single-family, multifamily, and transient units), and household size (1, 2, 3, 4, and 5+ persons per household). Trip production rates for home-based work, home-based shop, home-based social/recreation, and home-based other purposes are shown in Table 3.1. The original source for these trip production rates was the North Florida Household Travel Survey, consistent with the previous 2007 Alachua County model. These trip production rates were not updated since there is no updated household travel survey available at this time.

Trip attraction rates were originally derived from the 2005 Northeast Florida Regional Planning Model (NERPM). As the Gainesville Urbanized Area Transportation Study model and the Northeast Regional Planning Model are from Northeast Florida, both model regions share similar socioeconomic characteristics, such as less of a reliance on tourism and seasonal residents than other parts of Florida. The trip attraction rates and dwelling unit (DU) weights are kept the same as the 2007 Gainesville Urbanized Area Transportation Study model, as shown in Table 3.2 and Table 3.3, respectively. Again, these were kept unchanged since an updated source of trip attraction rates is not available. The 2010 small area demographic were not available at the time that this study was completed, so the dwelling unit weights were retained from the 2007 model.

The Alachua County 2010 model uses 11 trip purposes:

1. Home-based work;
2. Home-based shop;
3. Home-based social/recreation;
4. Home-based other (Home-based non-work, excluding university trips);
5. Non-home-based;
6. Home-based university;
7. UF campus/dorm;
8. Four-tire truck;
9. Single-unit truck;
10. Tractor-trailer; and
11. Internal-external.

Home-based university and University of Florida Campus/Dorm trip purposes are unique to the Gainesville Urbanized Area Transportation Study model. These additional purposes also were used in the Gainesville Urbanized Area Transportation Study 2007 and 2000 models. It is important to capture these trips in a university town, such as the City of Gainesville. The home-based university purpose is for trips traveling from off-campus housing to parking spaces within

the University of Florida Campus. On the other hand, the University of Florida Campus/Dorm trip purpose is trips from University of Florida on-campus dormitories to classrooms that are specified in the ZONEDATA file. It should be noted that the model has limited capabilities in simulating parking capacity beyond the number of parking spaces being stored in the ZONEDATA file and used in the attraction equations.

Home-based university and Dorm trip production and attraction equations for the Home-based university and Dorm purposes are listed below, as extracted from the model scripts. During validation, these trip rates were relocated to the Cube catalog keys (names depicted in {brackets}) to enhance model transparency.

Home-Based University Productions:
RO.HBUP = {RATE_HBUP}*ZI.1.UF_OC_ST
; UF_OC_ST is off-campus (students)
; Default value of {RATE_HBUP} is 2.996
Home-Based University Attractions:
RO.HBUA = {RATE_HBUA}*ZI.1.UF_PARKING
; PARKING is UF Parking Spaces
; Default value of {RATE_HBUA} is 1.375
UF Campus/Dorm Productions:
RO.HDORMUP = {RATE_HDORMUP} *ZI.1.UF_DORM_ST
; UF_DORM_ST is Campus housing/Dormitory students
; Default value of {RATE_HDORMUP} is 2.262
UF Campus/Dorm Attractions:
RO.HDORMUA = {RATE_HDORMUA} *ZI.1.SEATS
; SEATS is UF Classroom Seats
; Default value of {RATE_HDORMUA} is 0.7513

3.2 Socioeconomic Data and Traffic Analysis Zone Structure

Socioeconomic data is a very important input to the trip generation process. During the last model update in 2007, the ZDATA files were converted to the new Florida Standard Urban Transportation Model Structure file formats to be consistent with the Cube-Voyager scripting. The Gainesville Urbanized Area Transportation Study 2000 model used the NERGEN FORTRAN program for trip generation and relied on a number of ASCII text file formats for input data. The base year 2007 model used Cube-Voyager scripting in place of NERGEN FORTRAN routines and used input files in a database, rather than text format. As part of the 2010 effort, staff from the Metropolitan Transportation Planning Organization for the Gainesville Urbanized Area updated the 2007 socioeconomic data files to the new base year 2010, which were reviewed and refined by the consultant team in coordination with staff. Special generator and external trip files were updated by the consultant team.

Like the Gainesville Urbanized Area Transportation Study 2007 model, the 2010 model study area covers the entirety of Alachua County, including all nine municipalities within the county. The zonal structure of the 2007 model was reviewed by the consultant team and no changes were deemed necessary. The 2010 model has a total of 586 traffic analysis zones; 560 internal zones and 26 external zones within and outside study area. Figure 3.2 shows the Gainesville Urbanized Area Transportation Study travel demand model geographic coverage and the traffic analysis zone structure of the study area.

As mentioned earlier, staff from the Gainesville Urbanized Area Transportation Study developed the 2010 socioeconomic dataset which includes information on population disaggregated by single family, multifamily, and hotel/ motel units. It also provides information on auto availability, property vacancy rates, and seasonal use. On the employment side, the dataset contains information disaggregated by service, commercial, manufacturing, and other industrial sectors. It also contains information on school enrollment, university employment, dormitory students, and parking. The parking costs in the 2010 dataset were borrowed from the 2007 dataset based on discussions with staff from the Metropolitan Transportation Planning Organization for the Gainesville Urbanized Area.

Error! Reference source not found. and Figure 3.4 show the total population and employment of each traffic analysis zone within the regional travel demand model. The details of the SE data format are included in Appendix A of this report and the data is summarized in Table 3.4.

Table 3.4 Year 2010 Socioeconomic Data Summary

Socio-Economic data summary	2010
Permanent Population	247,336
Total Population	251,951
Permanently Occupied Dwelling Units	99,089
Transient and Permanently Occupied Dwelling Units	101,996
Total Service Employment	91,399
Total Commercial Employment	32,669

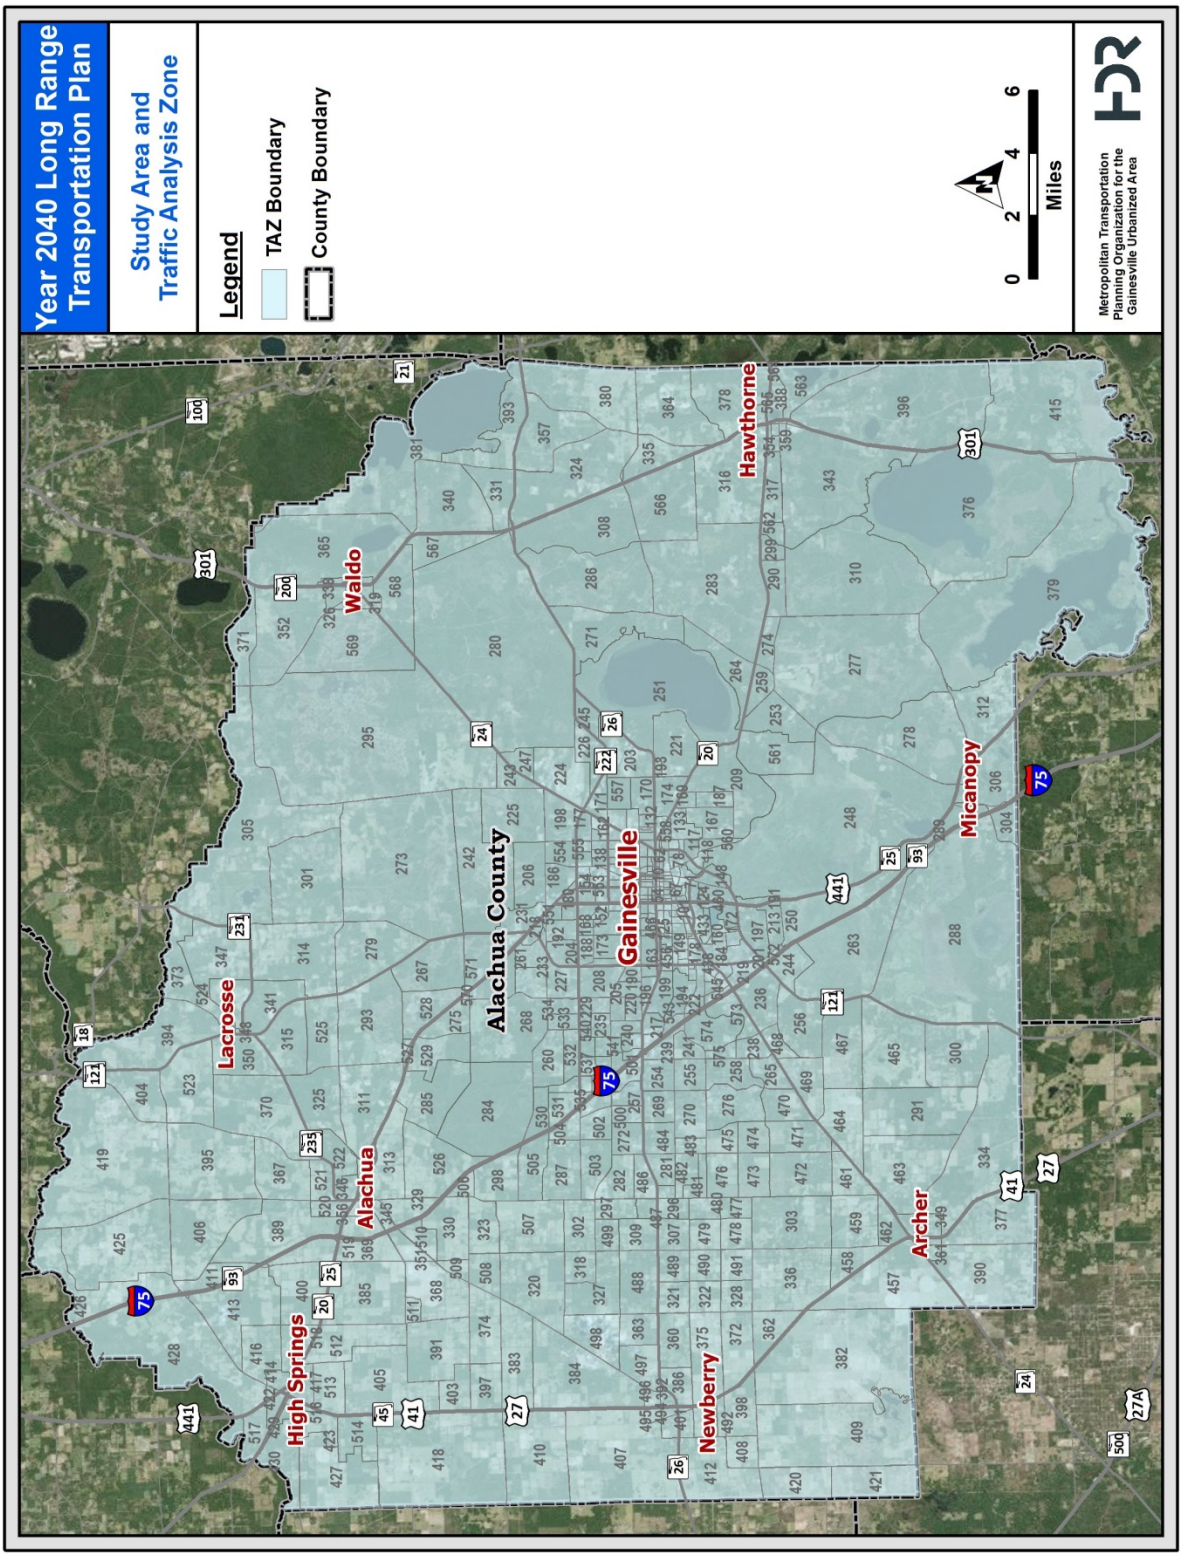

Figure 3.2 Study Area and Traffic Analysis Zone Structure

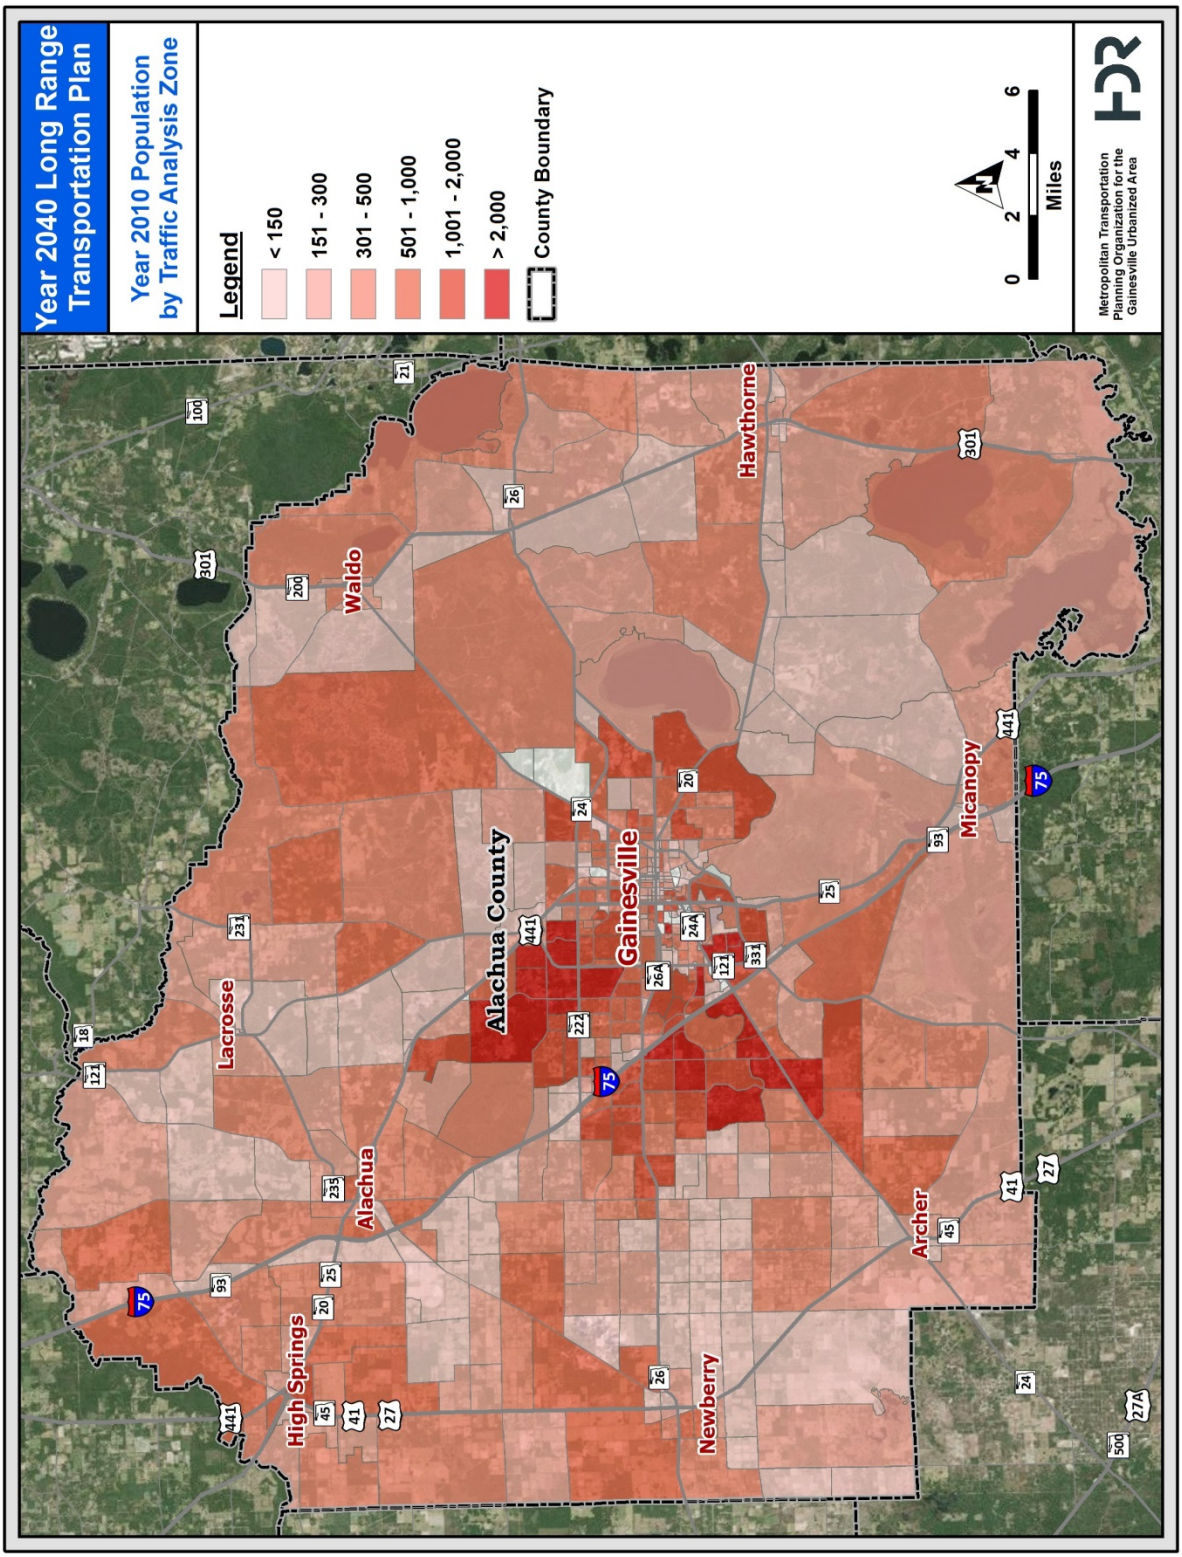

Figure 3.3 Year 2010 Population by Traffic Analysis Zone

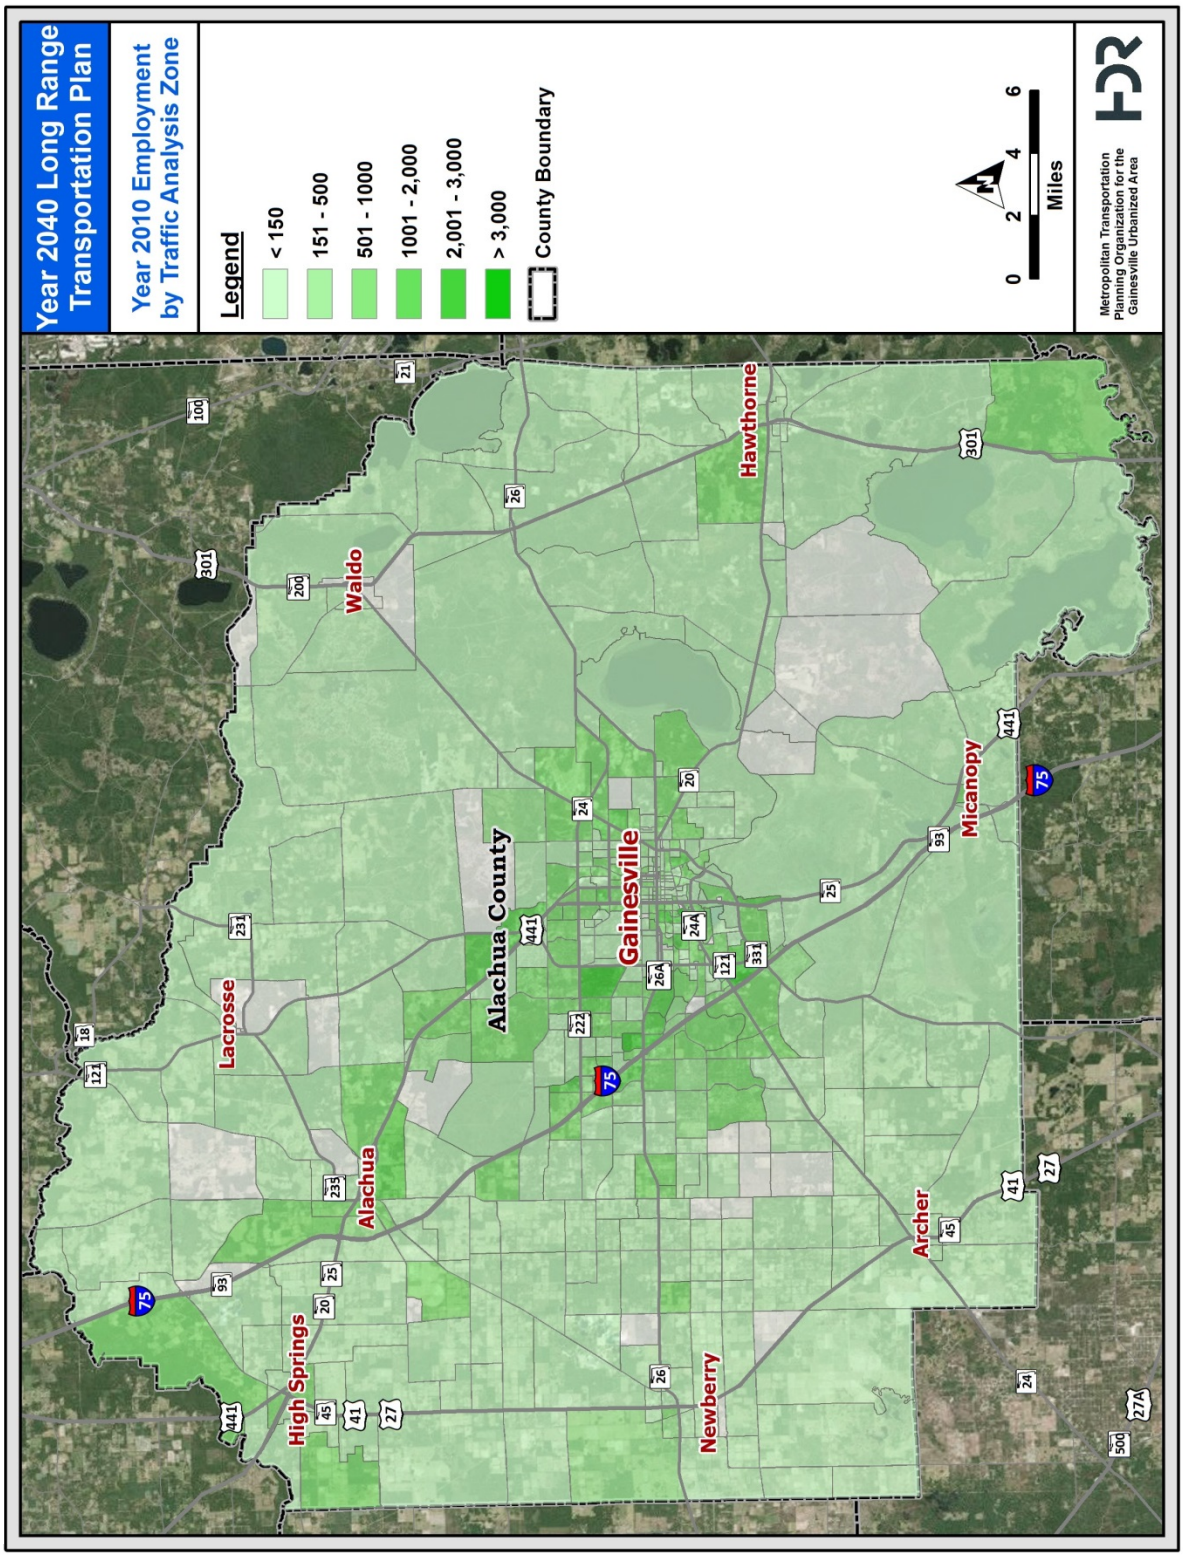

Figure 3.4 Year 2010 Employment by Traffic Analysis Zone

3.3 Special Generators

There are certain traffic analysis zones where the standard trip generation algorithms did not produce sufficient trips due to the special land use characteristics of these zones. These traffic analysis zones are called special generators. It is best practice in travel demand forecasting to minimize the use of special generators. Special generators should only be used where validation discrepancies exist that cannot be corrected with edits to other model files and parameters. The special generators are shown in Table 3.5.

Table 3.5 Special Generators

TAZ	PA dummy	Addition or Subtraction	Person Trips	HBW %	HBSH %	HBSR %	HBO %	NHB %	Description
536	A	+	27,000	2	2	2	92	2	Santa Fe College

460	A	+	362	20	38	38	0	4	University of Florida

TAZ = traffic analysis zone
PA = production/attraction
HBW = Home-based work
HBSH = Home-based shopping
HBSR = Home-based social-recreation
HBO = Home-based other
NHB = Non home-based

3.4 Trip Generation Validation Results

Throughout the validation process, trip generation statistics were summarized to assess model validity. Statistical comparisons were made between the Gainesville Urbanized Area Transportation Study 2007 and 2010 models as well as model validation standards from the *FSUTMS-Cube Framework Phase II: Model Calibration and Validation Standards Final Report*. The trip generation validation statistics is summarized in Table 3.6 and Table 3.7. As shown by the results, the trip generation estimated by the model is within acceptable ranges. Figure 3.5 and Figure 3.6 show the trip productions and attractions by traffic analysis zone.

Table 3.6 Percent Trips by Purpose

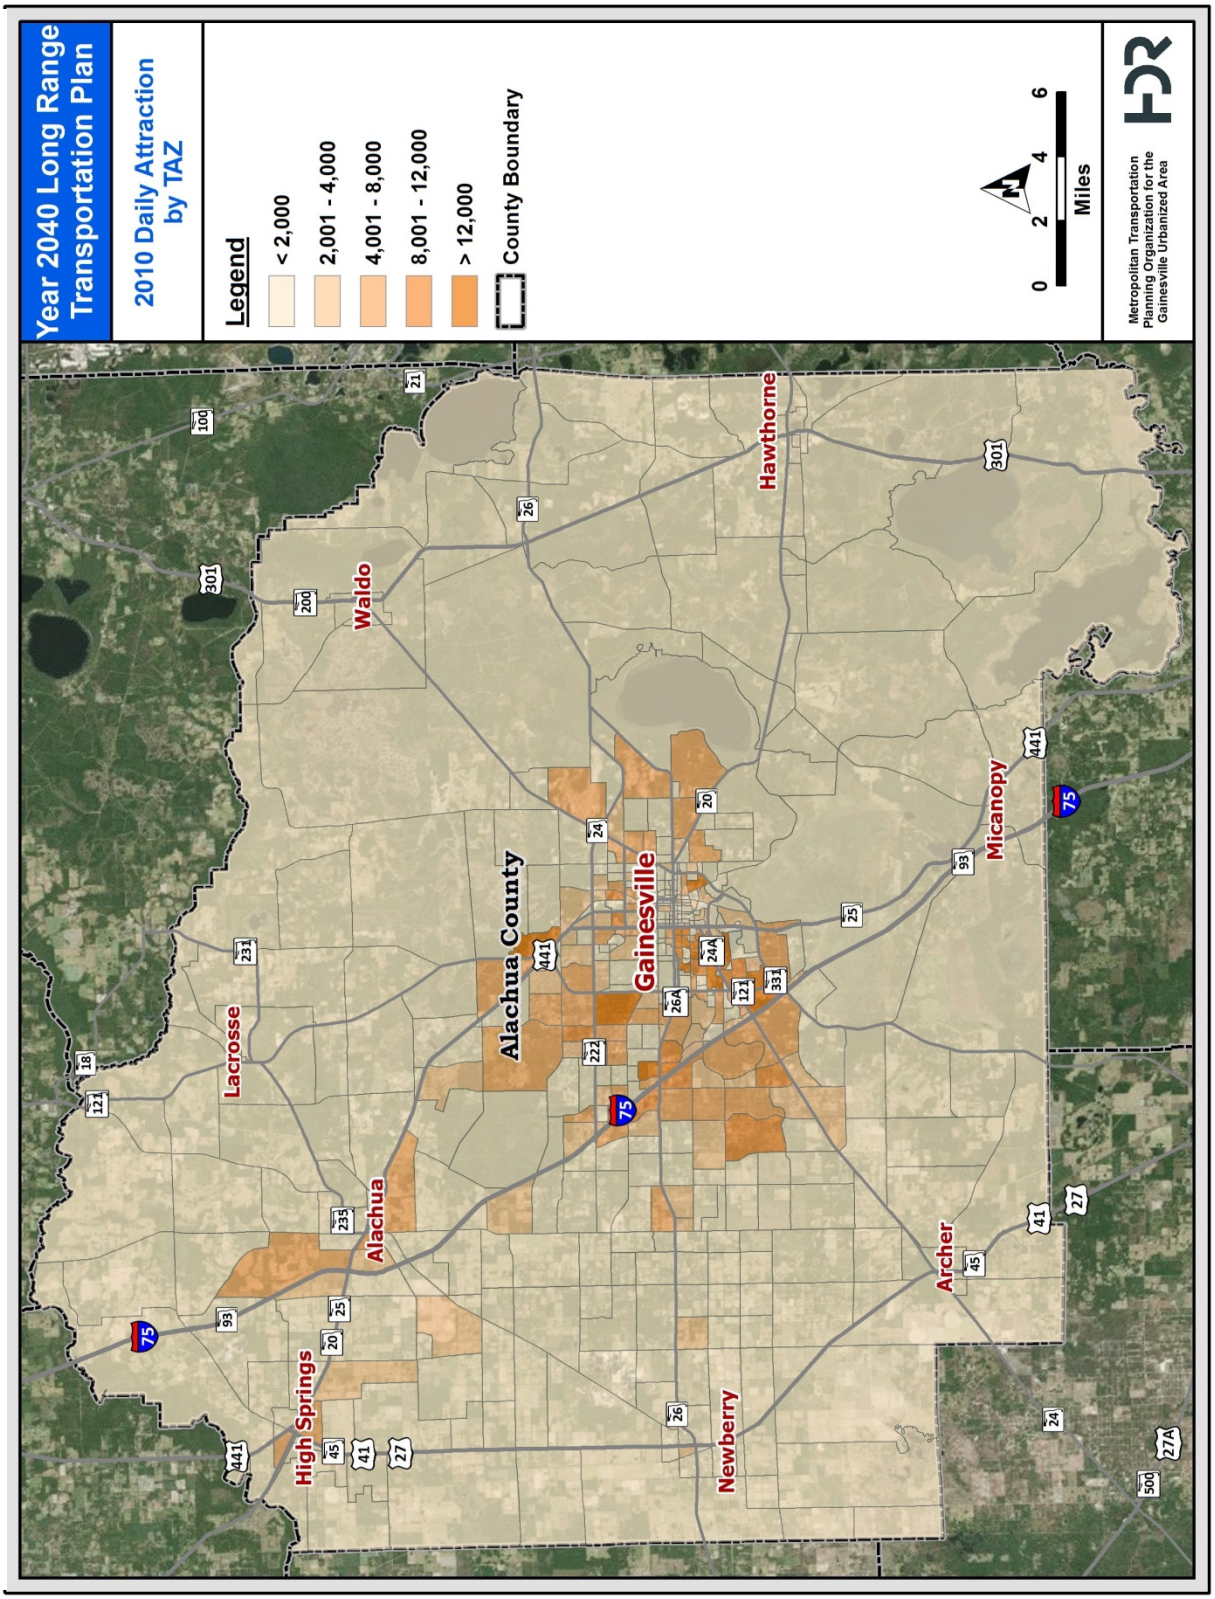

Figure 3.6 Year 2010 Trip Attractions by Traffic Analysis Zone

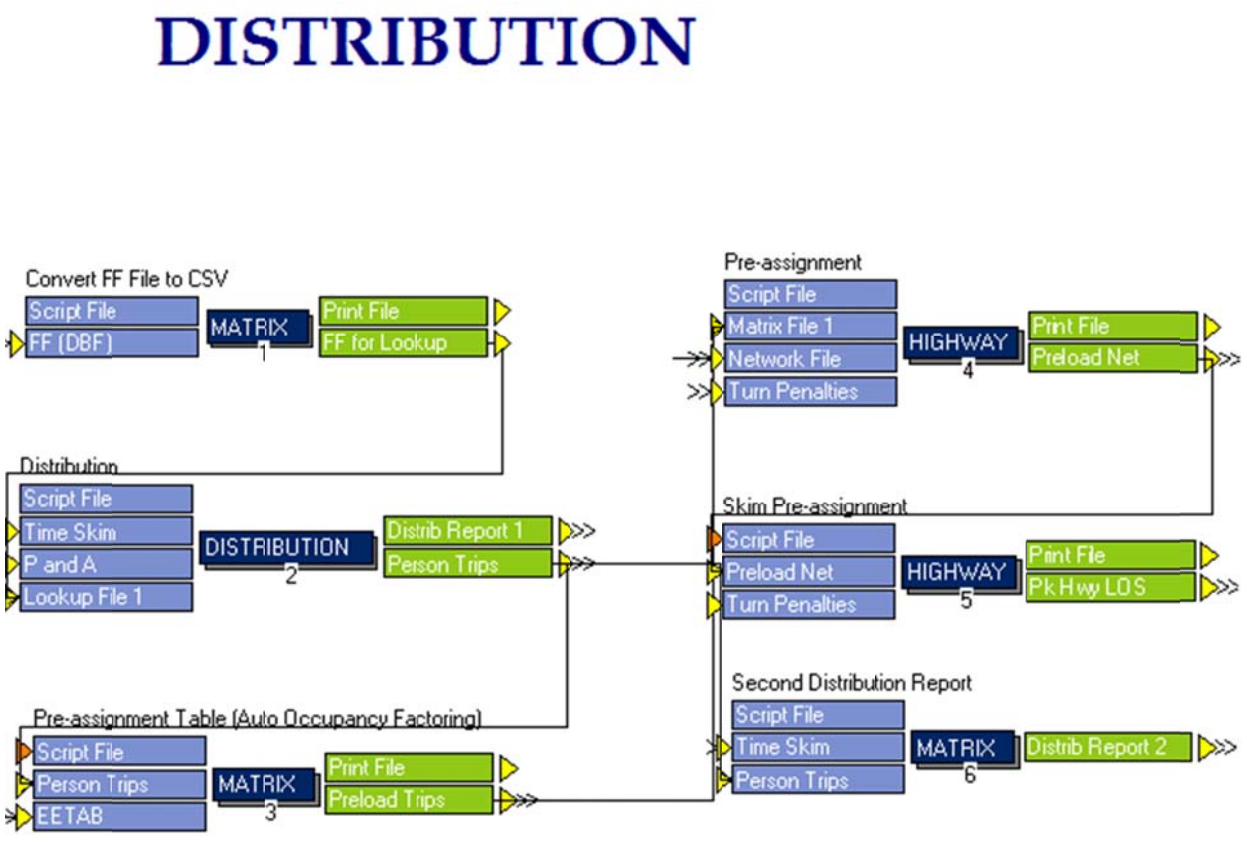
4 Trip Distribution

Trip distribution models link trip productions and attractions between pairs of traffic analysis zones. The most common method for trip distribution in four-step models is the gravity model. The trip distribution step distributes all trips produced in a zone to all possible attraction zones using a gravity model. The gravity model uses the trip productions and attractions estimated in the trip generation model and the network friction to distribute the trips. Friction factors are used to represent the effects of travel impedance. Friction factors can be computed by a formula, such as gamma function, or can be calibrated such that a modeled trip length frequency distribution matches an observed trip length frequency distribution. Trip distribution results in person trip matrices detailing the trips between each production and attraction traffic analysis zone. These person trips matrices are later processed in the model chain during mode choice to allocate trips by auto occupancy and transit categories. Figure 4.1 shows the trip distribution model chain.

Figure 4.1 Trip Distribution Model Chain



For evaluation of trip distribution, the *FHWA Travel Model Validation and Reasonability Checking Manual* recommends two general types of aggregate checks of trip distribution model results - trip length checks and origin-destination pattern checks. For this model, evaluation was accomplished by comparing statistics for average trip length and the percentage of intrazonal trips between the Gainesville Urbanized Area Transportation Study 2010 model, the Gainesville Urbanized Area Transportation Study 2007 model, and the Florida Standard Urban Transportation Model Structure standards. Additionally, desire line maps were prepared to show travel movements between zones and trip length frequency distributions were reviewed for reasonableness.

4.1 Trip Distribution Model Structure

The general distribution process includes the building of highway networks and travel time skims as well as application of the gravity model. The elements of these processes are described below.

Building Highway Networks

The Florida Standard Urban Transportation Model Structure includes a module known as "Highway Network" to process highway networks of model areas. As part of the model validation process, the consultant conducted an in depth review of the highway network. Network characteristics (number of lanes, area type, and facility type) were updated to reflect 2010 conditions of the roadway system throughout Alachua County.

Travel Time Skims

Free-flow travel time skims between zone pairs are developed as the last substep in the "Highway Network" module in the Florida Standard Urban Transportation Model Structure, including the updating of travel time skims with intrazonal and terminal times. Highway network characteristics are an input to this process. In addition to the highway network characteristics, other input files are generally used during network skimming. The first of these is the turn penalties file which contains a record of all prohibited turning movements in the network. Turning movements were reviewed to include any updated prohibited movements for year 2010 conditions during validation. The turn penalty file can also include time penalties; however, time penalties were not recommended in the model area as the highway assignment validated reasonably well without supplemental travel time factors. Also, a toll file is used in most Florida models to identify toll plaza characteristics. However, because no toll roads exist

in Alachua County, this file is not used in the Gainesville Urbanized Area Transportation Study 2010 model.

Intrazonal times represent the travel time it takes to travel within or across a zone. These times are calculated as one-half the average travel time from each zone to the two nearest adjacent zones. Terminal times represent the time required at either end of a trip to travel from an origin to a vehicle or from the vehicle to a final destination. More specifically, this accounts for the time necessary to walk to or from the vehicle used for any given trip. Terminal times are typically greatest in central business districts and lowest in residential areas. Table 4.1 lists the terminal times by area type used in the Gainesville Urbanized Area Transportation Study 2010 model.

Table 4.1 Terminal Times

Terminal Times*	Area Type	Area Type Descriptions
5	12	Urbanized Area (under 500,000) Primary City Central Business District
5	13	Other Urbanized Area Central Business District and Small City Downtown
5	14	Non Urbanized Area Small City Downtown
3	21	Central Business District Fringe Areas
3	22	Industrial
1	31	Residential Area of Urbanized Areas
1	32	Undeveloped Portions of Urbanized Areas
1	33	Transitioning Areas/Urban Areas over 5,000 Population
2	42	Other Outlying Business District
1	51	Developed Rural Areas/Small Cities under 5,000 Population
1	52	Undeveloped Rural Areas

*Terminal Times listed in whole minutes

Trip Distribution Module

The "DISTRIBUTION" module distributes trips between zones using a gravity model. The primary input data used for DISTRIBUTION are the friction factor (FF) file and a set of congested highway skims. These are used by the gravity model to measure the effects of spatial separation between zones for the purposes of trip distribution. It is generally assumed that productions are less likely to be linked to destinations with greater travel times if alternative destinations with lesser travel times and similar attractiveness are available. Friction factors from the Gainesville Urbanized Area Transportation Study 2007 model were used for the Gainesville Urbanized Area Transportation Study 2010 model without modification. Since no new household travel surveys were conducted since the 2007 model calibration and validation,

and the resulting trip distribution was reasonable, it was decided to maintain the existing friction factor set in the 2010 model.

Friction factors are used by the gravity model to link the trip productions and attractions generated by GENERATION. These trip interchanges denote person trips traveling from one zone in the model to another. Trips are distributed by the trip purposes found in the Gainesville Urbanized Area Transportation Study 2010 model. These person trips are later converted into vehicle trips during mode choice and then loaded onto networks during highway and transit assignment. The next subsection describes the checks, modifications, and adjustments made to trip distribution assumptions in order to verify and improve model validity.

4.2 Trip Distribution Model Development and Validation

Errors in the trip distribution phase can lead to significant problems in the execution of following steps in the model chain (i.e., mode choice and trip assignment). Consequently, efforts were taken to maximize the accuracy of the Gainesville Urbanized Area Transportation Study 2010 trip distribution module. These efforts included adjustments to network speeds and capacities and corrections of network link attributes.

Speeds and Capacities

The speed and capacity look up table is the same as the 2007 model; the main effort for validating the capacity was to update the number of lanes for the highway network. The Florida Department of Transportation Roadway Characteristics Inventory has been used as the primary source for updating the number of lanes to represent the 2010 conditions.

Penalties and Prohibitions

The TURN.pen file, formerly known as TCARDS, allows for the adjustment of travel times on specific links by either including a time penalty to pass from one link to another or by prohibiting the movement all together. Prohibitions are confined to ramps located along Interstate 75, mainly to guide trips to the correct ramps for each travel movement. No time penalties were added during the 2010 model validation effort. The TURN.pen file is listed in Appendix B.

Friction Factors

Friction factors are used in the gravity model to represent the effects of travel impedance. These factors define the measure of separation based on travel impedances between traffic analysis zones. The friction factors from the 2007 model were reviewed and no updates were necessary for the 2010 model validation. Analysis of the trip distribution summaries did not indicate a need for modification in order to improve trip distribution. Average trip lengths seemed reasonable, intrazonal percentages made sense, and aggregate trip distribution patterns looked logical. Furthermore, there are no updated household travel diary survey data for Alachua County to allow for calibration of new friction factors. A copy of the validated friction factor file (FF.dbf) is listed in Appendix C.

4.3 Trip Distribution Validation Results

Based on the Florida Standard Urban Transportation Model Structure standards, three gravity model checks were developed. They are average trip length by purpose, percentage of intrazonal trips and trip flow patterns/ trip length frequency distribution.

Average Trip Length by Purpose

Table 4.2 shows a comparison of average trip length statistics generated by the 2010, 2007, and 2000 Gainesville Urbanized Area Transportation Study models, and Florida Standard Urban Transportation Model Structure standards. Comparisons between the 2010 and 2007 Gainesville Urbanized Area Transportation Study models show a small trip length increase in home-based university, truck-taxi and Internal-External. All other categories of trips have shorter trip lengths than 2007. Overall, the trip lengths are very similar to the 2007 model. Although the average trip lengths are on the low side compared to the Florida Standard Urban Transportation Model Structure standards, this is to be expected given the relatively smaller region covered by the Gainesville Urbanized Area Transportation Study model.

Table 4.2 Average Trip Lengths (in Minutes)

Purpose	2010 Alachua County	2007 Alachua County	2000 Alachua County	FSUTMS*
Home-Based Work	14.67	14.73	13.92	15-28

Intrazonal Trip Distribution

Comparisons between the 2010 and 2007 Gainesville Urbanized Area Transportation Study models indicate that the percentage of intrazonal trips is similar for most trip purposes. These results are illustrated in Table 4.3.

Table 4.3 Intrazonal Trip Summary

	Alachua County 2010			Alachua County 2007			FSUTMS*
Purpose	Total Trips	Intrazonal Trips	Percent	Total Trips	Intrazonal Trips	Percent	
Home-Based Work	185,977	2,640	1.42%	183,288	2,783	1.52%	1-4%
Home-Based Shop	135,794	4,894	3.60%	132,443	5,585	4.22%	3-9%
Home-Based Social/Recreation	120,814	8,953	7.41%	119,642	9,302	7.77%	4-10%
Home-Based Other	270,787	10,457	3.86%	252,428	10,971	4.35%	3-7%
Non-home-Based	354,049	24,913	7.04%	329,119	23,675	7.19%	5-9%
Home-Based University	64,423	35	0.05%	75,940	39	0.05%	NA

Internal-External	101,867	0	0.00%	114,055	0	0.00%	NA
Total	1,340,533	54,518	4.07%	1,311,684	54,880	4.18%	3-5%

* Table F.1 - FSUTMS-Cube Framework Phase II Model Calibration and Validation Standards

Trip Flow Patterns and Trip Length Frequency Distributions

The model area trip flow pattern analysis is another aggregate visualization check in the validation process. Traffic analysis zone-to-traffic analysis zone trip flows were conducted and checked with local knowledge to verify the reasonableness of trip distribution. In Figure 4.2, traffic analysis zone-to-traffic analysis zone daily total trip flows obtained from the model are represented by desire lines. Only daily trip flows that are greater than 20 trips are shown. The concentration of trip desires in the downtown area and general radial patterns make intuitive sense given the land use patterns of Alachua County. Figures 4.3 through 4.6 show the trip length distribution by purpose - the 2007 and 2010 trip length frequency distributions are found to be very similar.

In summary, the 2010 trip distribution validation results are consistent with the 2007 model and within acceptable Florida Standard Urban Transportation Model Structure standards.

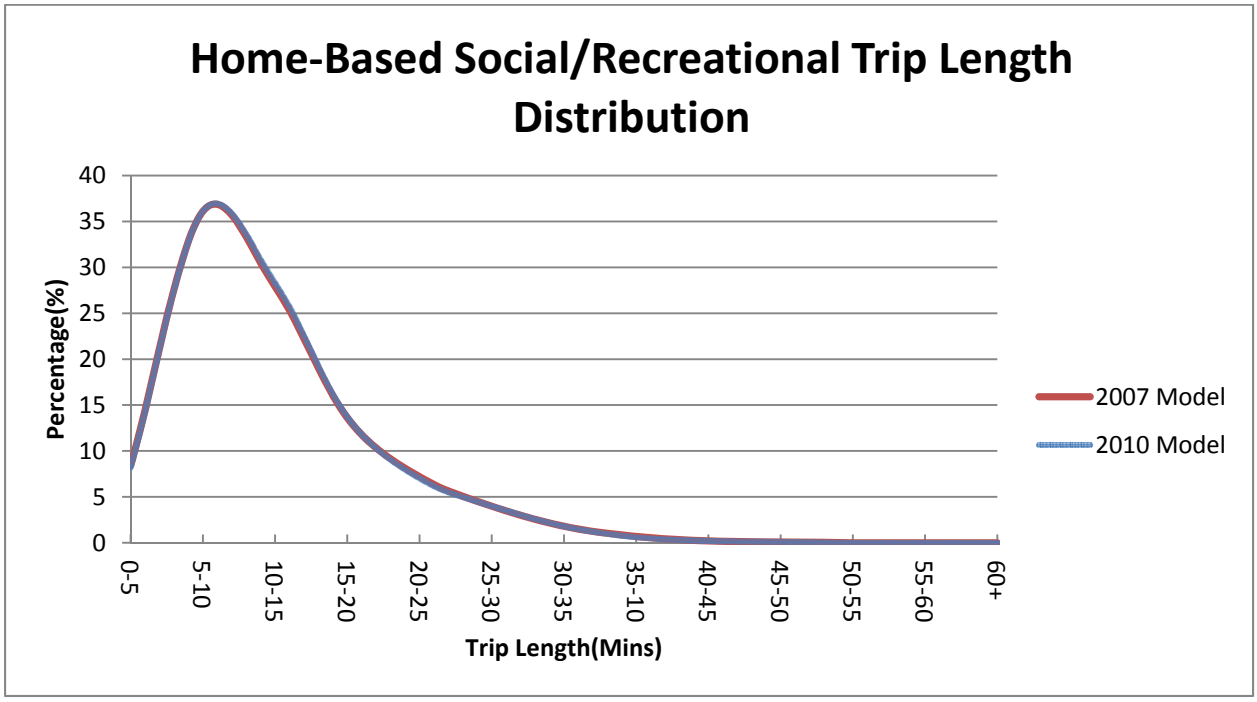

Figure 4.6 Trip Length Frequency Distribution for Home-Based Other

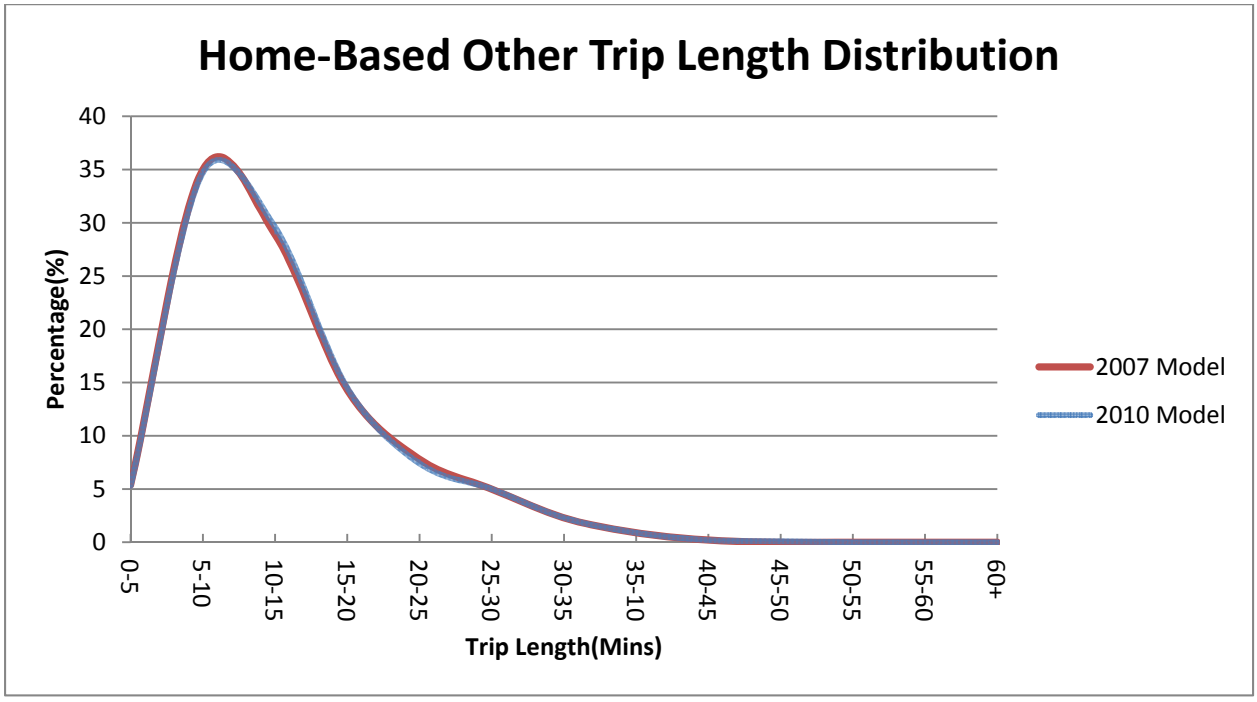
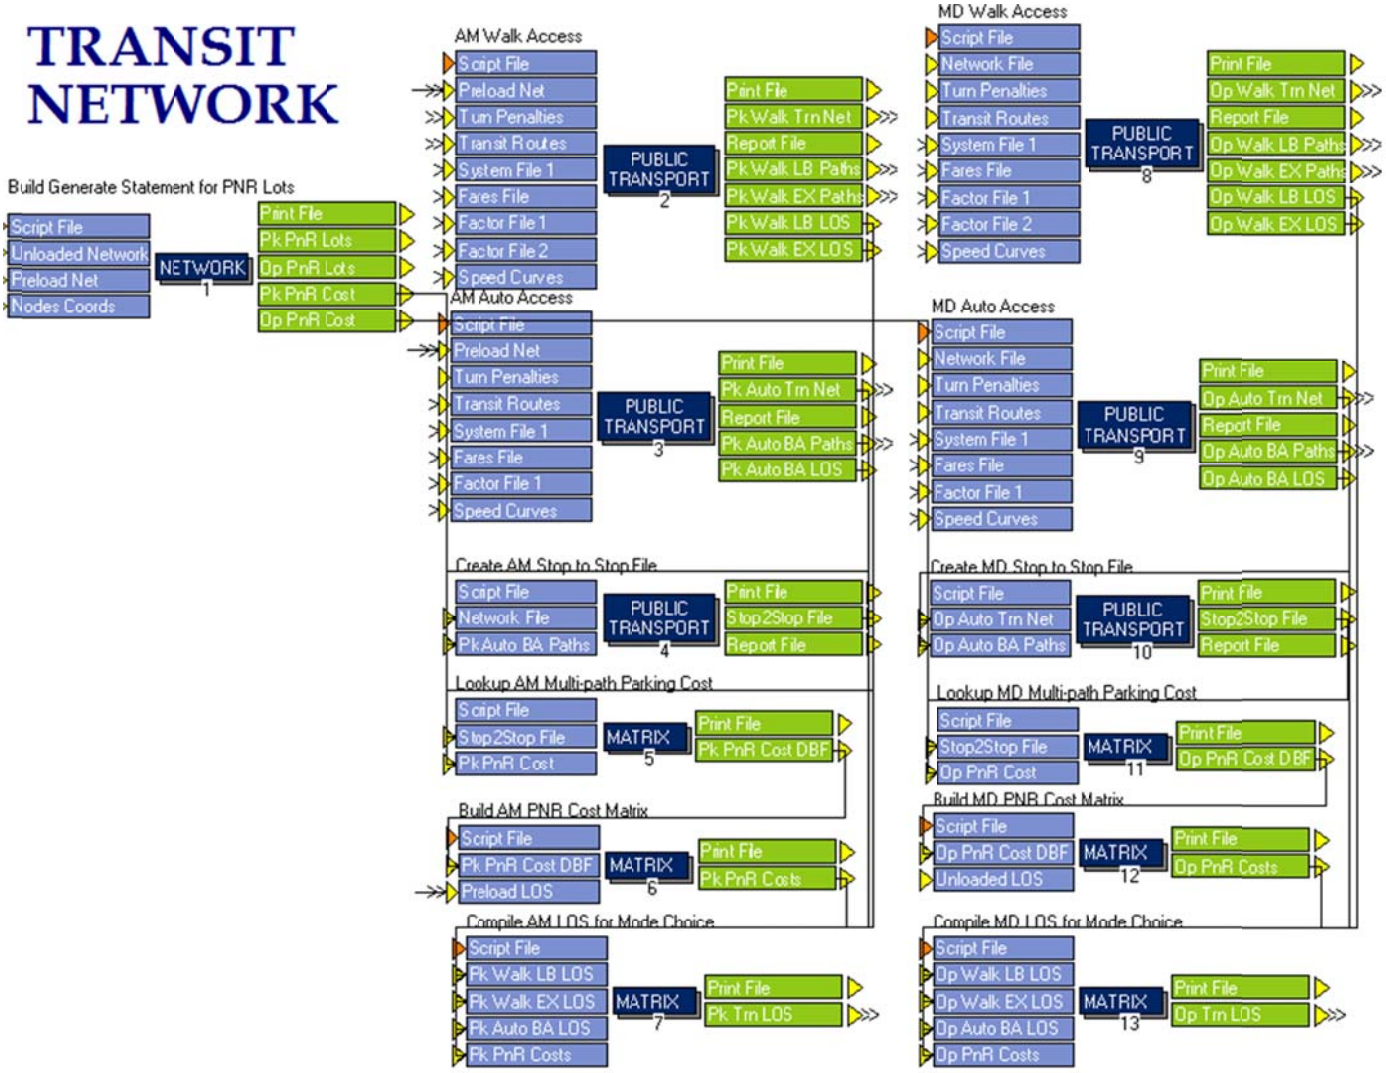


5 Transit Accessibility and Path-Building

Integral to the building of a transit network is the availability of access to transit. A critical component of transit access is identifying the zones that are within an acceptable walking distance to a transit stop. Walk access is generally provided from centroids to stops within a specified distance. Transit path-building involves the transit fares, transit routes and stops/stations. These inputs are used for each of the transit modes during peak and off-peak periods used in the model. The Alachua County 2010 model currently only has one transit mode, local bus, but has the capability of expansion to other transit modes in the future. Figure 5.1 shows the structure of transit network module.

Figure 5.1 Transit Network Module



5.1 Transit Access and Path-Building Module Structure

The Florida Standard Urban Transportation Model Structure transit network module is used to establish transit access and path-building. The module constructs separate peak-period (AM) and off-peak (MD) transit networks using congested highway networks as an input to produce transit vehicle travel times. Transit path-building involves the generation of transit path skim matrices, fares, and station-to-station interchanges.

Transit accessibility is represented by each zone's pedestrian environment variables (PEV) that are stored in the ZONEDATA file. The pedestrian environment variables define several factors that are essential to have sufficient accessibility to bus stops, such as sidewalk availability, ease of street crossing, non-motorized connections, and building setbacks. Each variable is given a score between 0 and 3 and the accumulated scores of the four pedestrian environment variables are saved as "SUM" in the ZONEDATA file, which ranges from 0 to 12. Future changes to the zonal transit accessibility will require modification of pedestrian environment variable scores as well as updating "SUM" values to get total pedestrian environment variable scores for each traffic analysis zone. Table 5.1 indicates what each pedestrian enhancement variable value represents. These variables and categories remain unchanged from the 2007 model.

Table 5.1 Pedestrian Environment Variables

Variables	PEV = 0	PEV = 1	PEV = 2	PEV = 3
Sidewalk Availability	No sidewalks	<10 percent have sidewalks	10 to 90 percent have sidewalks	>90 percent have sidewalks
Ease of Street Crossing	Crossing difficult	<10 percent have easy crossing	10 to 90 percent with easy crossing	>90 percent with easy crossing
Non-motorized Connections	No connections	<10 percent have connections	10 to 90 percent have connections	>90 percent have connections
Building Setbacks	All large setbacks	<10 percent have minimum setbacks	10 to 90 percent have minimum setbacks	>90 percent have minimum setbacks

5.2 Transit Access and Path-Building Model Development and Validation

Most of the effort in validating the transit accessibility and path-building focused on ensuring that the transit network was up to date and accurately reflected base year conditions. In addition, walk access links were checked in order to ensure adequate connectivity.

Transit Accessibility

The key effort in validating the transit network consisted of three parts. The first was to review the existing transit network and update it to year 2010 operating conditions. This required significant additions and rerouting of the transit lines. The second part was to check that there is no "Later Gator" bus route coded around the University of Florida campus since this may result in over assignment. Finally, pedestrian environment variables in the ZONEDATA file were reviewed and updated for each zone. However, because of limited data availability, the pedestrian environment variables are generally kept the same as 2007.

Transit Fare

The Gainesville Regional Transit System (RTS) transit fare was $1.00 during the year 2007, used for the Gainesville Urbanized Area Transportation Study base year 2007 model validation. This fare was increased to $1.50 in 2010, according to the Gainesville Regional Transit System. Details on how the bus fare was adjusted during validation are further explained in Transit Procedure and Assignment section. The fare has been set to $1.50 for base year 2010 in ALACHUA.FAR file. For the future year transit analysis, the bus fare factor (BUSSFAREFAC) value may need to be updated to represent fare increases beyond inflation.

Transit Routes

As validation efforts moved towards reasonable transit assignments, transit network rerouting, bus stop locations and local zonal access to bus stops were reviewed using the Gainesville Regional Transit System General Transit Feed Specification files. Headway data was also extracted from the Gainesville Regional Transit System General Transit Feed Specification files and the transit route file (troute10.lin) was updated. The transit route file had to be overlaid on the highway network when new bus locations were added due to the necessity of splitting highway links where a bus stop exists. The highway network was therefore updated at the same time as the transit route file was updated. "Later Gator" bus routes are not included in the 2010 Alachua County model as these are evening bus services specifically for University of Florida students and operate for only limited hours while the model is designed to estimate daily peak and off-peak transit ridership.

Transit Skimming Parameters

The path parameters used during transit skims were reviewed for reasonableness and consistency with mode choice coefficients. Consistency between skimming and mode choice is

an area that is considered by the Federal Transit Administration (FTA) when a model is used for New Starts or Small Starts purposes. A few skim parameters were identified (in the 2007 model) that were not consistent with mode choice. Auto driving time to park and ride lots had a perceived weight parameter of 1.0 in the 2007 model skim parameters while the ratio of out-of-vehicle travel time to in-vehicle travel time in mode choice is 2.0 for home-based work. Also, transfer waiting time had a perceived weight parameter of 1.4 in the 2007 model. Both of these skimming parameters were set to 2.0 in the 2010 model for consistency with mode choice.

5.3 Transit Access and Path-Building Model Validation Results

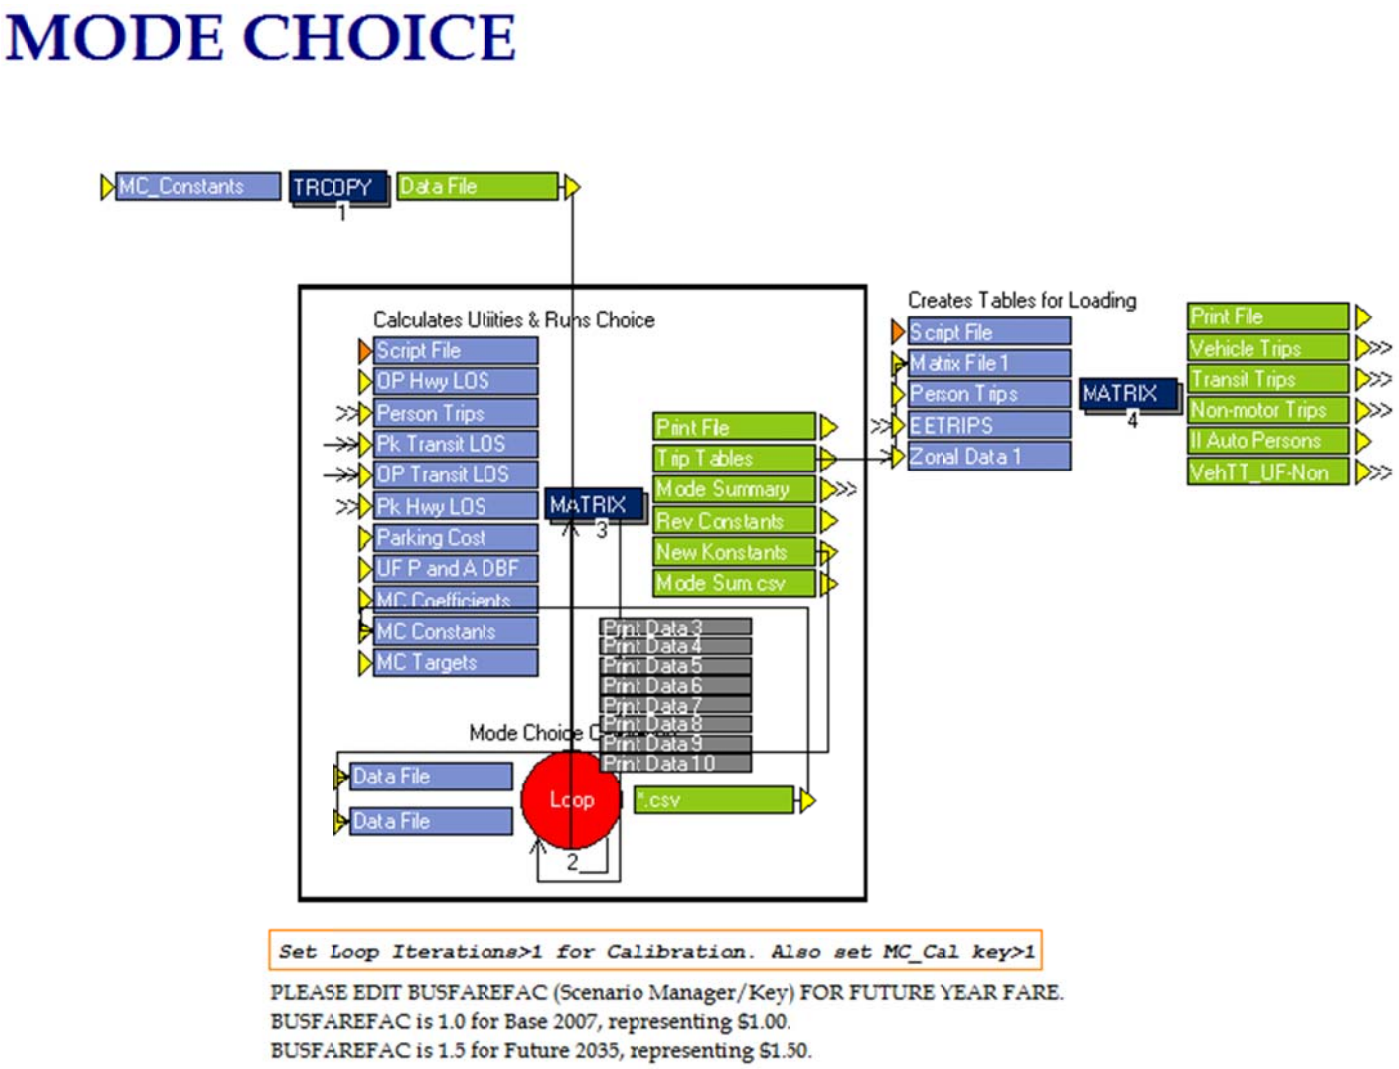
The Federal Transit Administration has noted that certain common practices in transit path building can have undesired impacts on ridership forecasts. Minimum and maximum values of time and distance used to determine valid transit paths and modal availability can have unexpected effects. Path building parameters and settings should remain the same for all steps of the model (skimming, assignment). All transit parameters in the model were reviewed for consistency across the model chain. The careful review of all transit parameters ensured reasonableness of transit access and path building.

Average weekday transit trips in the year 2010 computed from the data provided by the Gainesville Regional Transit System were 41,535. The model currently is estimating an average of 40,403 transit riders per day, which is only 2.7% lower than observed data and is well within the acceptable range of 3% - 9% from the Florida Standard Urban Transportation Structure standards. Additional details on transit assignment are provided in Section 8.0 of this report.

6 Mode Choice

Since Alachua County is the home of University of Florida and Santa Fe Colleges, like other college towns the transit system plays an important role in daily transportation and needs to be considered in modeling. The mode choice model used in the 2010 Alachua County model is a set of nested logit models that estimate modal shares among several categories of auto and transit modes. This section of the report describes the structure and validation of the mode choice model. Figure 6.1 shows the structure of this part of model.

Figure 6.1 Mode Choice Model Chain



6.1 Mode Choice Model Structure

The Florida Standard Urban Transportation Model Structure process makes use of a nested logit model for mode choice, except in the case of highway only models (i.e., those that do not include transit networks). The entire mode choice process is executed via Cube/Voyager scripting, using the MATRIX program.

One script, MCMAT00A.S, creates a trip table matrix set containing trips for all five purposes: home-based work (HBW), home-based other (HBO), non-home-based (NHB), home-based university (HBU) and University of Florida Campus/Dorm (DORM). The trip tables for each purpose are separated into 8 mode specific tables: auto drive-alone (DA), auto 2-person carpool (CP), auto 3+ person carpool (CX), walk to local bus (WB), walk to premium bus (WX), drive to transit (BA), walk (WK), and bike (BK). Transit skim data compiled in the transit network module and highway skims generated during trip distribution are inputs into the "MODE" module. The peak period utilizes the congested highway skims, whereas the off-peak period uses the free flow skims.

After running the mode choice model, the outputs are balanced into origin and destination trip tables. A separate script, MCMAT00C.S, combines trip purposes and outputs separate trip tables for the following modes and these trip tables are then used during the highway and transit assignment phases of the model:

1. Drive alone auto;
2. Carpool auto;
3. Light duty trucks;
4. Heavy duty trucks;
5. External-external trips;
6. Peak period transit;
7. Off-peak period transit;
8. Non-motorized travelers; and
9. Internal auto persons (combination of modes 1 and 2, above).

A few minor changes were made to fix the deficiencies embedded in the 2007 mode choice script. Since the unit of the fare cost is dollars while other costs (like parking) are using cents as the unit, fare cost needs to be multiplied 100 to become comparable to other costs. This was not correctly done for some of the trip purposes in the 2007 model. The scripts referenced above and others pertaining to Mode Choice can be found in Appendix D, along with the corresponding model flowchart for each step.

6.2 Development and Validation of Mode Choice Model

The mode choice model step for the Gainesville Urbanized Area Transportation Study 2010 model was developed from the Gainesville Urbanized Area Transportation Study 2007 model, with a few changes to mode choice scripting (MCMAT00A.S). The constants file (MCCONSTANTS.CSV) was modified with recalibration of the transit trips. Coefficients (MCCOEFFICIENTS.CSV) are kept the same as 2007 and are in a numeric range consistent with current Florida Standard Urban Transportation Model Structure validation standards. The mode choice coefficients were not revised given that a better source of data, such as a new household travel survey, is not available. All parameters are shown in Table 6.1.

Table 6.1 Mode Choice Coefficients for 2010 Model

Mode Choice Model Parameters	2010	FSUTMS
Home-Based Work IVTT	-0.025	-0.01 to -0.05
Home-Based Non-Work IVTT	-0.02	-0.007 to -0.033
Non-Home Based IVTT	-0.024	-0.01 to -0.05
University IVTT	-0.024	-0.02 to -0.03
Home-Based Work OVTT	-0.049	NA
Home-Based Non-Work OVTT	-0.048	NA
Non Home-Based OVTT	-0.07	NA
University OVTT	-0.048	NA
Home-Based Work OVTT/IVTT	2.0	1.5 to 3.0
Home-Based Non-Work OVTT/IVTT	2.4	2.0 to 6.0
Non Home-Based OVTT/IVTT	2.9	2.0 to 7.0
University OVTT/IVTT	2.0	2.0 to 3.0

*IVTT = in-vehicle travel time, OVTT = out-vehicle travel time

6.3 Mode Choice Model Results

Mode choice results were compared with statistics from Census American Community Survey data for the home-based work (HBW) trip purpose. With respect to transit mode split, the Gainesville Urbanized Area Transportation Study 2010 mode split percentages were smaller than the 2007 model for the home-based work purpose. The home-based work purpose showed 4.18 percent of all home-based work trips being transit as opposed to 4.39 percent for the 2007 model. The 2010 results are reasonable compared to the transit mode share estimate from the American Community Survey (refer to the end of Table 6.2). In total, 2.38 percent of all trips in the 2010 model were allocated to transit modes while 2.17 percent of all trips in the 2007 model were allocated to transit. Table 6.2 contains the Gainesville Urbanized Area Transportation Study 2010 model Mode Choice validation results.

Table 6.2 Mode Choice Validation Summary

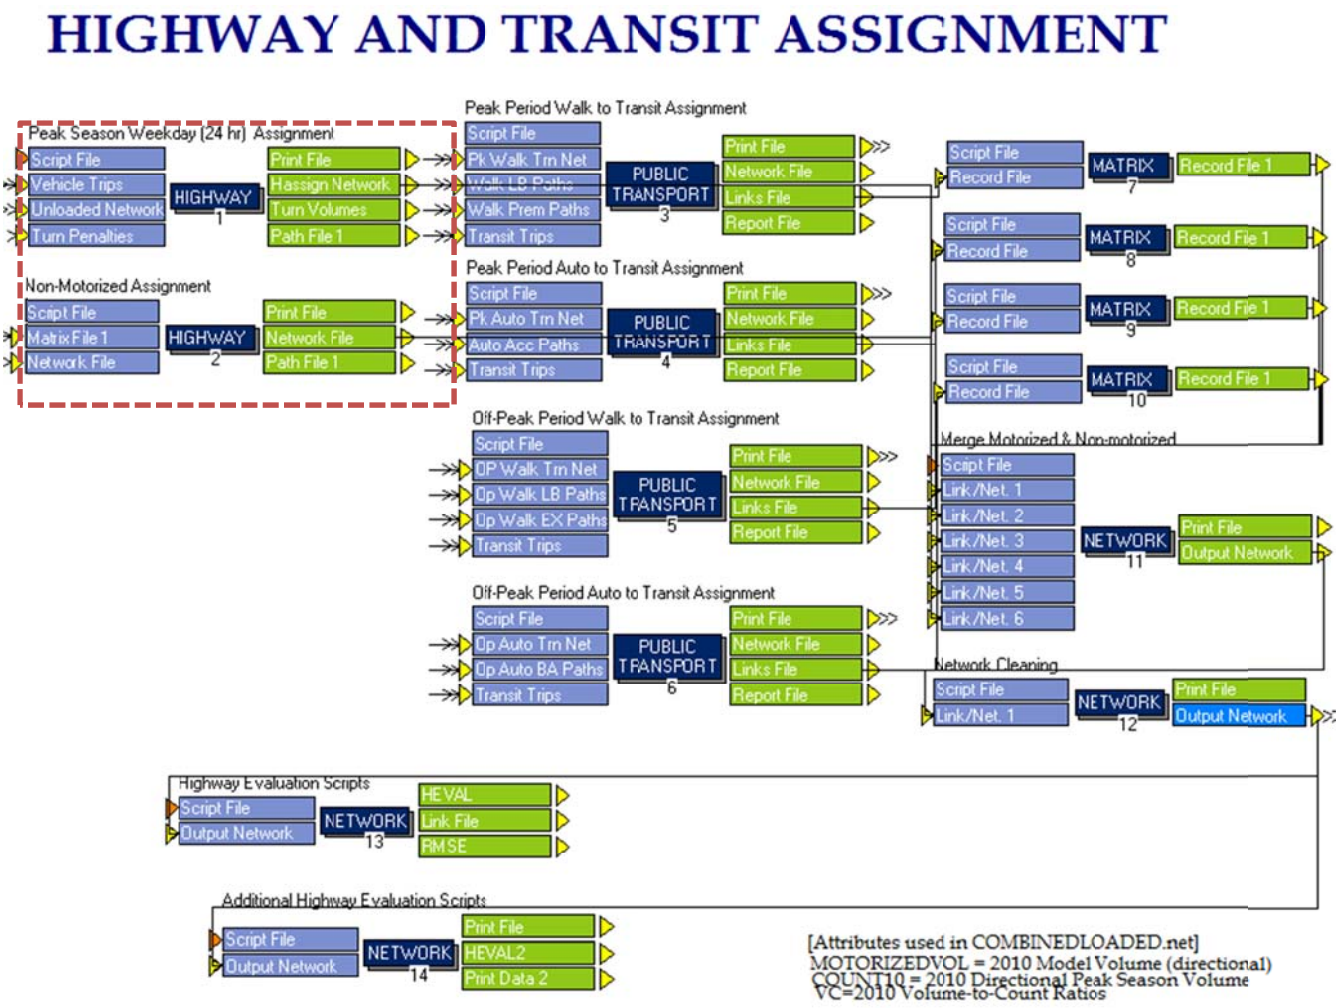
7 Highway Assignment

A proper validation of the highway assignment is critical to the meaningful use of travel demand models. The objective of the assignment module is to load trips to available paths to achieve system equilibrium. Highway trip assignment determines the shortest path between any given origin destination pair and loads the auto trips produced by the mode choice module onto those path links. The trips are loaded incrementally – once the first iteration is completed, link travel times are then recomputed, the new shortest paths are subsequently determined, and the next iteration is executed. This process proceeds through a series of iterative calculations until no one can shorten their travel time by changing routes. In another words, system equilibrium is achieved at the end of highway assignment. The red dotted line in Figure 7.1 shows the highway assignment model chain. Highway assignment is combined with transit assignment at this model. The details of transit assignment will be discussed in next chapter.

Figure 7.1 Highway Assignment Module



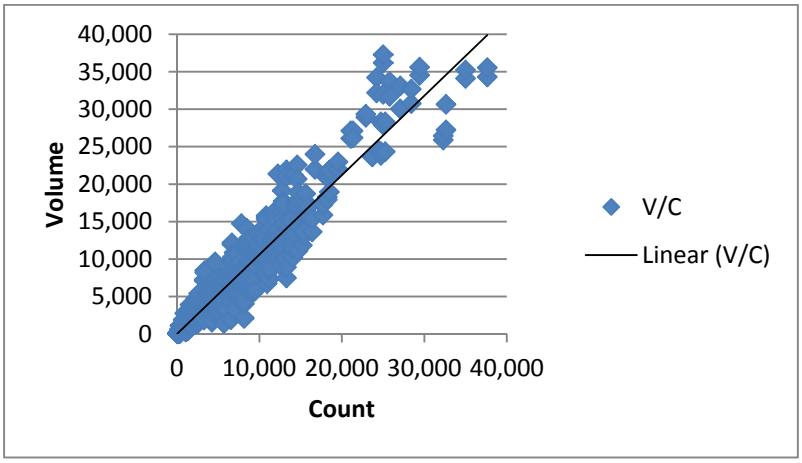
7.1 Highway Assignment Procedure

Auto trips are loaded onto the network by means of an iterative equilibrium highway load program based on an all or nothing assignment algorithm. In total, six model runs were executed in order to validate the Gainesville Urbanized Area Transportation Study 2010 model, excluding numerous test runs that were necessary for iterative adjustment and minor calibration. Adjustments were made to key elements of the modeling process to achieve satisfactory validation results. After each run, a summary of the results was compiled and analyzed in order to identify areas for improvement in the model and successful strategies toward validation enhancement. A number of key evaluation statistics, which are recommended by the *FSUTMS- Cube Framework Phase II: Model Calibration and Validation Standards Final Report*, were generated for model calibration and validation purposes. Model validation was accomplished by minimizing the difference between the model estimated volumes and observed traffic counts for the year 2010 on network segments for the entire study area.

7.2 Highway Assignment Validation Results

The evaluation of the highway assignment module is based on comparisons between observed traffic counts and model estimated volumes. Base year model estimated traffic volumes are compared to the 2010 traffic counts in different ways to determine whether the model projections are reasonable. Figure 7.2 shows a volume to count scatter plot for the overall model. The indicators that are available for determining the overall performance of the highway assignment model are volume to count ratios by area type/ facility type/ lane categories, screen line volume over count ratios, and root mean square error (RMSE). Each of the measures is discussed in the remainder of this section.

Figure 7.2 Volume to Count Scatter Plot



Assignment Performance by Area Type/Facility Type/Lanes Categories

Table 7.1 contains details of the volume-over-count ratios for each link group category by area type, facility type, and number of lanes. At the area-wide level, the 2010 base year model is overestimating volumes by 6 percent.

Screenline Performance

Analyzing volume-over-count ratios along screenlines allows for examining traffic flows across geographic subareas and corridors. Florida accuracy standards along screenlines have historically varied from +/-5 percent to +/-20 percent. There are 10 screenlines in the Alachua County 2010 model including an external cordon line measuring trips coming into and going out of the study area.

Table 7.2 shows volume to count ratios by screenline (note that double counting of trips was avoided in creating the summary). Figure 7.3 shows the locations of the screenlines. Screenline 9 does fall slightly outside of the FSUTMS standard. However, this validation effort was focused on the overall region wide calibration.

Table 7.1 Volume to Count Performance by Category

Category	2010	Florida Standard Urban Transportation Model Structure		Number of Links

Percent Root Mean Square Error

Root Mean Square Error is among the most commonly reported statistics in model validation. Root Mean Square Error, a measure of dispersion, tends to normalize model error better than volume-over-count ratios that allow for high ratios to offset low ratios. Table 7.3 shows the Root Mean Square Error statistics by volume group. All categories met stablished accuracy standards.

Table 7.3 Root Mean Squared Error

Volume Range	2010 Model	Florida Standard Urban Transportation Model Structure	
		Acceptable	Preferable
1-5,000	47.1%	+/-100%	+/-45%
5,000-10,000	28.5%	+/-45%	+/-35%
10,000-20,000	23.4%	+/-30%	+/-25%
20,000-30,000	23.0%	+/-27%	+/-15%
30,000-40,000	11.7%	+/-25%	+/-15%
Average Total	31.3%	+/-45%	+/-35%

8 Transit Procedure and Assignment

The transit procedure in the Gainesville Urbanized Area Transportation Study 2010 model includes development of transit input data, building transit path, calculating the number of transit trips from the mode choice model, and loading the transit trips to the transit network. Each of these four aspects of the transit procedure is discussed in this document.

The development of the transit input data was discussed in Section 5. Information on routes, stop locations, service characteristics, and ridership was provided by Gainesville Regional Transit System staff. Detail transit network coding and review was conducted in order to ensure that the system representation in the model is accurate. The ridership data was utilized to assess the reasonableness of the model outputs.

A detailed review of all transit parameters including path building was conducted and documented. Transit levels of service are computed separately for peak hours and off-peak hours. During the process of distribution, the preloaded highway network with pre-assignment loads based on initial time skim is created. Then in the process of transit path creation, the preloaded network is used to calculate the time skim for transit during peak hours. Transit vehicle speed (link travel time) is determined as a function of the automobile speed on each link. The type of relationship used for each transit service type is identified based on area type and facility type of the link. These auto/transit speed relationships are used in a lookup function to assign speeds for transit paths. Then the transit travel time is calculated proportionally according to relative relationship between auto travel times. During this step, path files with shortest time and distance for peak and off-peak are also created which are later used at the transit assignment stage. Other variables, like headway, transit accessibility, waiting time and transit path building parameters are assigned to each route during this process as well.

The Gainesville Urbanized Area Transportation Study 2010 model uses a nested logit model approach for mode choice. Variables that are considered include in-vehicle transit time, out-of-vehicle transit time, cost, bike or walk to transit time, and pedestrian environment variables. The coefficients used in mode choice for these variables are shown in Table 8.1. For home-based work trips, the local bus fare is discounted to 25% since there is an employee pass program. This 25% factor was retained from the 2007 model, and was originally computed to match model computed home-based work ridership to observed ridership. Since the transit fare is covered by tuition fees of University of Florida students the local bus fare for home-based university and dorm-university walk to local transit is discounted to 10%. For home-based university walk and drive to premium transit the bus fare is free. The percentages of each

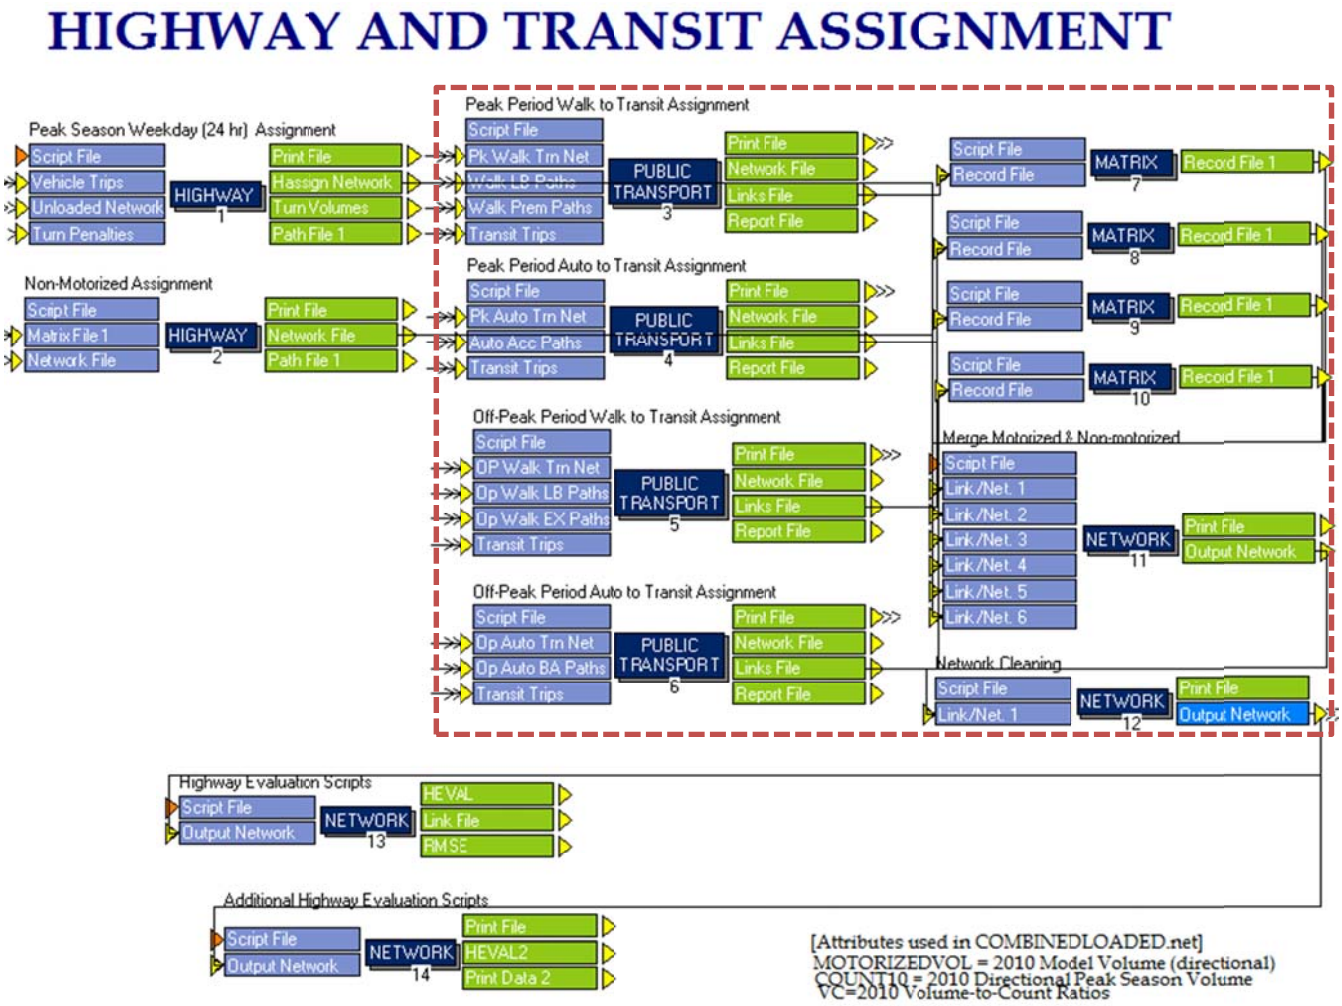
mode are calculated by using nested logit mode choice. The details of the mode choice model validation are discussed in Section 6.

Table 8.1 Mode Choice Coefficient for Transit Variables

Coefficient	Home-based Work	Home-based Other	Non home-based	University
civt - In-Vehicle Transit Time Coefficient	-0.025	-0.02	-0.024	-0.024
covt – Out-of-Vehicle Transit Time Coefficient	-0.049	-0.048	-0.07	-0.048
ccst - Cost Coefficient	-0.005	-0.011	-0.009	-0.011
cwt - Walk only Coefficient	-0.042	-0.083	-0.052	-0.083
cbt - Bike Coefficient	-0.109	-0.117	-0.096	-0.117
pti - Walk to Transit Pedestrian Enhancement Variable Coefficient	1.15	0.6	0.45	0.25
pwi - Walk Pedestrian Enhancement Variable Coefficient Origin	0.35	0.175	0.22	0.4
pwj - Walk Pedestrian Enhancement Variable Coefficient Destination	0.3	0.164	0.164	0.35
pbi - Bike Pedestrian Enhancement Variable Coefficient Origin	0.47	0.07	0.066	0.3
pbj - Bike Pedestrian Enhancement Variable Coefficient Destination	0.006	0	0.006	0.006

The last step in the process is to assign the transit trips to the routes. Separate loads are conducted by mode and period as allocated in the mode choice model. Home-based work trips are assigned to the peak period network while home-based other, non-home-based, home-based university, and dorm-university trips are assigned to the off-peak network. Within each period there are three transit mode choices available: walk to local bus, walk to express bus, and drive to best available transit. The transit assignment flow is relatively simple in this model. It loads the transit trips from mode choice onto the transit paths computed during path building. There are no parameters used in this procedure. The red dotted square in Figure 8.1 shows the transit assignment module.

Figure 8.1 Transit Assignment Module



8.1 Transit Assignment Validation Results

Not nearly as much effort is typically expended on transit assignment validation as is devoted to highway assignment validation, in part due to transit assignment not impacting roadway congestion or capacity, as well as a general lack of post-processing programs and scripts to summarize transit assignment accuracy. However, transit is a key component of the Gainesville Urbanized Area Transportation Study 2010 model and it is important to validate the transit assignment reasonably well at the system level at a minimum. The transit assignment step in the model chain loads person trips onto the transit network. Separate loadings are conducted by mode and period: home-based work trips are assigned to the peak period network while home-based other, non-home-based, home-based university, and dorm-university trips are assigned to the off-peak network.

Overall validation for transit assignment was based on an analysis of the transit ridership not only as a system but also on a route by route basis. Transit assignment loadings were compared to average weekday "unlinked" route ridership data provided by Gainesville Regional Transit System. Unlinked trips are equal to bus boardings and count all the times that a person boards a bus, both initially and during transfers.

Table 8.2 shows route level comparison of observed ridership and ridership estimated by the model. The 2010 Gainesville Regional Transit System weekday ridership was calculated using the average of the months when school is in session during 2010 (excluding summer months of June, July, and August). The average weekday ridership during the summer months is much lower than the rest of the year. Since the model forecasts include university trips, it is reasonable to use average weekday ridership from September to May for comparison purposes.

The Gainesville Urbanized Area Transportation Study 2010 model trips are the number of transit trips loaded to each route by the transit assignment module. System-wide model estimates of unlinked trips are very close to Gainesville Regional Transit System observed numbers. As shown on Table 8.2, the 2010 transit assignment model estimated 40,403 "unlinked" riders system wide, while the Gainesville Regional Transit System reported 41,535 average weekday ridership system wide for 2010 while school was in session.

At the system-wide level, ridership for the Gainesville Urbanized Area Transportation Study 2010 model differs by only 2.7 percent from data provided by Gainesville Regional Transit System. This is within the preferred 3-9 percent Florida Department of Transportation validation standard. On a route-by-route basis, the 2010 transit assignment model validates

well with 26 out of 36 bus routes performing within the preferred accuracy range, and 29 of 36 within the acceptable range. In general, regional models do not validate well on a route by route basis. More rigorous validation is conducted for specific transit studies (New Starts/ Small Starts projects for example) or other ridership forecasting tools are applied (for example, TBEST is typically applied for transit development plans). Nonetheless, the Gainesville Urbanized Area Transportation Study 2010 model performs well in transit assignment at the system-wide level and performs reasonably well on a route-by-route basis.

Appendix D contains the model script files and flowchart for transit assignment. These show the processes, input parameters, and output file locations.

9 Summary and Conclusions

The model validation phase of the Gainesville Urbanized Area Year 2040 Long Range Transportation Plan Update began with data development and review which was documented in Technical Reports 2 and 3. Data review, adjustment, and correction were an iterative process throughout the model validation effort, reflecting identification of data issues based on model results.

Once the input data were initially deemed sufficient to proceed, work continued on validating each component of the Gainesville Urbanized Area Transportation Study 2010 travel demand model. An activity log was created to record all the modifications made to the model and a validation spreadsheet was prepared and used to summarize each validation run and model performance against prior versions of the Gainesville Urbanized Area Transportation Study model as well as other comparable travel demand models. This updated validation worksheet incorporates the latest Florida Department of Transportation model validation accuracy standards and allows for a complete record of all model adjustments made during the validation effort and the resulting impacts. The highway side of the model validated reasonably well from the start, largely a reflection of the efforts put forth by the study team in data development, review, disaggregation, and refinement.

The Gainesville Urbanized Area Transportation Study 2010 base year model meets most established Florida Standard Urban Transportation Model Structure standards for model accuracy and reasonableness. The validated model will be used in subsequent phases of the Gainesville Urbanized Area Year 2040 Long Range Transportation Plan Update to develop and test transportation alternatives.

Appendix A: Socioeconomic Data Format

ZONEDATA{YEAR}.DBF

Notes: Please note that ZONEDATA{YEAR}.DBF is part of GIS TAZ shape database of ZONEDATA.SHP, together with ZONEDATA.SHX. When editing this ZoneData file, Cube or GIS software must be used.

Attribute List for Population and Household Data

TAZ_2010 – Traffic Analysis Zone (TAZ) number in the Gainesville MTPO 2010 model.
SFDU – Number of single-family dwellings units
SPOP – Population in single-family dwellings units
MFDU – Number of multifamily dwellings units (MFDUS)
MPOP – Population in MFDUS
TOTPOP10 – Total population for year 2010 (this attribute is not used by model scripts, instead SPOP and MPOP are used for base year and future year scenarios)
HMDU – Total hotel–motel units
HMPOP – Total population in occupied hotel-motel units

Attribute List for Employment Data

OIEMP – Other industrial employment
MFGEMP – Manufacturing industrial employment
COMEMP – Commercial employment
SERVEMP – Service employment
TOTEMP – Total employment
SCHENR – School enrollment by school location (this excludes any UF or Santa Fe College enrollment)

Attribute List for University of Florida Data

UF_EMP – Number of UF place-of-work employees by TAZ (this variable also is used to reallocate service employment on UF Campus)
UF_DORM_ST – Number of on-campus UF student residents
UF_PARKING – UF commuting parking spaces, excluding on-campus student long-term
CLASSROOMS – Number of UF classrooms (model scripts do not use this)
CLASSSQFT – Square feet of UF classrooms (model scripts do not use this)
SEATS – Number of UF classroom seats
UF-OC-ST – Number of UF off-campus students, estimated from student address records provided by UF
SUB_AREA – Name of city or incorporated area or Alachua if a zone is within the unincorporated area
UFZONES – Identifier that indicates that a zone is on UF Campus when the value is one

Attribute List for Transit PEV (Pedestrian Environment Variable) Data

SIDEWALK – Sidewalk availability (values vary from 0 to 3)
CROSSING – Ease of street crossing (values vary from 0 to 3)
NONMTR_CNN – Non-motorized connections (values vary from 0 to 3)
SETBACK – Building setbacks (values vary from 0 to 3)
SUM – Sum of four variable values above: SIDEWALK, CROSSING, NONMTR_CNN and SETBACK (SUM needs to be updated manually when any of four variables has been modified)
COMPOSIT – composite PEV value (model scripts do not use this)
SELECTZONE – Identifier that indicates that a zone is selected for select zone analysis when the value is one (the model will load selected trips that end at the selected zones, and it will be reported

in the attribute SELZONE_MOTOR in the final highway assignment output network, COMBINEDLOADED.NET)
HOTEL – Identifier used in the previous model (model scripts do not use this)

Attribute List for Parking Data (previously found in ZDATA2 file in 2000 model)
SHORTPARK – Short-term (3 hour) parking cost (cents)
LONGPARK – Long-term (8 hour) parking cost (cents)
STUDENTPAR – Student (8 hour) parking cost (cents) at UF

Attribute List for Population and Household Variable Data (previously found in ZDATA1 file in 2000 model)
SF_SEA – Percent SFDU not occupied by permanent residents
SF_0V – Percent households having no vehicles in SFDU occupied by permanent residents
SF_1V – Percent households having one vehicle in SFDU occupied by permanent residents
SF_2V – Percent households having two vehicles in SFDU occupied by permanent residents
SF_3V – Percent households having three or more vehicles in SFDU occupied by permanent residents
SF_VAC – Percent SFDU vacant
MF_SEA – Percent MFDU not occupied by permanent residents
MF_0V – Percent households having no vehicles in MFDU occupied by permanent residents
MF_1V – Percent households having one vehicle in MFDU occupied by permanent residents
MF_2V – Percent households having two vehicles in MFDU occupied by permanent residents
MF_3V – Percent households having three or more vehicles in MFDU occupied by permanent residents
MF_VAC – Percent MFDU vacant
HM_POC – Percent hotel-motel units occupied

Appendix E: Input and Output Network Format

Input Network Format (HNET20{YEAR}.NET)

Note: {YEAR} represents the last two digits of the scenario year. The file name will be HNET2010.NET if it is base year 2010 scenario or HNET2040.NET if it is 2040 Existing plus Committed scenario.

Attribute List for HNET20{YEAR}.NET

Link Attributes

A – A node
B – B node
SCRN – FSUTMS screenline code
DIR – Direction code (0=two-way, 1=one-way)
FTYPE – FSUTMS two-digit facility type. It also should be noted that any link present in the network with FTYPE=0 will not be carried through the model.
ATYPE – FSUTMS two-digit area type
LANES – Directional number of lanes
ROAD_NAME_ – Street name
ROAD_NAME2 – Alternate street name
TYPE – Represents if it is a U.S., state or county road if applicable
RCIFCLASS – RCI functional classification
DISTANCE – Link length in miles
BK_LNS – Bike lanes code (0 = no bike lanes, 1 = in street bike lanes, 2 = wide buffers for biking, 3 = off-street multipurpose facilities)
MOCF – Model output conversion factor that is found from FDOT Traffic Info DVD
AADT07 – Year 2007 two-way average annual daily traffic estimate, only for links where the count was available. For I-75 this is the sum of both directions.
COUNT07 – Directional traffic count with MOCF applied. This is used when VC (volume-to-count ratio) is calculated in the output network.
AADT10 – Year 2010 two-way average annual daily traffic estimate, only for links where the count was available. For I-75 this is the sum of both directions.
COUNT10 – Directional traffic count with MOCF applied. This is used when VC (volume-to-count ratio) is calculated in the output network.

Node Attributes

N – Node number
X – X coordinate
Y – Y coordinate
PNRDESCRIP – Bus park-and-ride lot description (text)
PNRSVCAREA – Maximum park-and-ride service area (highway access distance), in miles.
PARKINGSPA – Number of park-and-ride lot parking spaces. This value is optional because the model does not constrain the auto access mode by the number of spaces.
PNRTERMTIM – Park-and-ride terminal time (walk time from the auto to the bus stop).
KNRTERMTIM – Kiss-and-ride (auto drop-off) terminal time (walk time from the auto to the bus stop).
AMUSEFLAG – Flag to turn the lot on or off for the AM or peak network. If “1”, the lot is used, if “0”, the model ignores the lot.
AMPNRCOST – Cost in cents to park for AM (peak) park-and-ride trips.
MDUSEFLAG – Flag to turn the lot on or off for the MD or off-peak network. If “1”, the lot is used, if “0”, the model ignores the lot.

MDPNRCOST – Cost in cents to park for MD (off-peak) park-and-ride trips

Output Network Format (COMBINEDLOADED.NET)

Note: All the input attributes that were included in the input network of HNET20{YEAR}.NET are carried over to the output network.

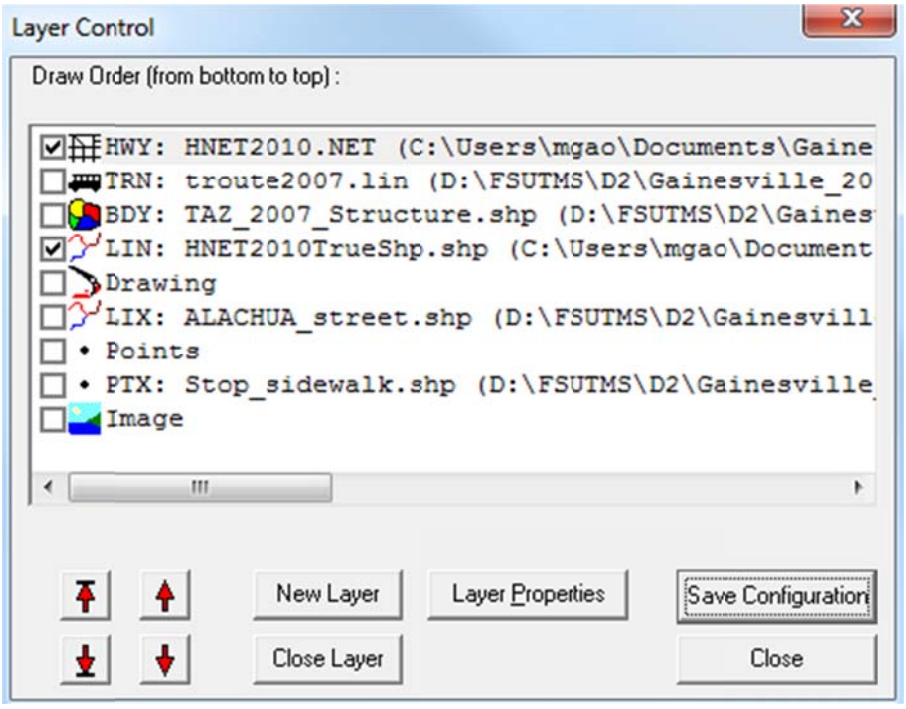
Attribute List for COMBINEDLOADED.NET

NONMOTORVOL – Total nonmotorized volumes
CGSPEED – Congested speed
CGTIME – Congested travel time (minutes)
SELZONE_MOTOR – Select zone volumes if ZoneData{YEAR}.DBF included the value of one in the SELECTZONE attribute.
UF_MOTOR – Light plus heavy vehicles with a UF trip end
LIGHTVEHICLES – Total light vehicles
HEAVYTRUCKS – Total heavy trucks
MOTORIZEDVOL – Light vehicles plus heavy trucks (MOTORIZEDVOL is most important because it is directional assigned auto volume that is used for highway evaluation)
VMT – Total motorized vehicle miles of travel.
VHT – Total motorized vehicle hours of travel.
PEDESTRIANS – Pedestrian volumes.
BICYCLISTS – Bike volumes.
VOL_CAP – Motorized volume/ (FSUTMS LOS C capacity)
DAILYCAPE– Daily FSUTMS LOS E capacity
VOL_CAPE – Motorized volume/ (FSUTMS LOS E capacity)
TranVol – Total transit volume (daily persons)
VC – 2010 Volume-to-Count Ratio (VC=MOTORIZEDVOL/COUNT10) This is only available in the base year 2010 scenario.
CONFAC – percentage of daily traffic occurring in the peak hour from VFACTORS.
CAPACITY – Hourly link capacity from the FSUTMS Speed-Capacity table, multiplied by the number of lanes
DAILYCAP – Daily capacity for roadway assignment
SPEED – Free-flow speed from the FSUTMS Speed-Capacity table. If needed, free-flow travel time in minutes can be calculated as: TIME=60*DISTANCE/SPEED
WALKTIME – Travel time in minutes for walk trips at 2.5 miles per hour.
BK_SPD – Bicycle speed
BK_TIME – Bicycle travel time in minutes

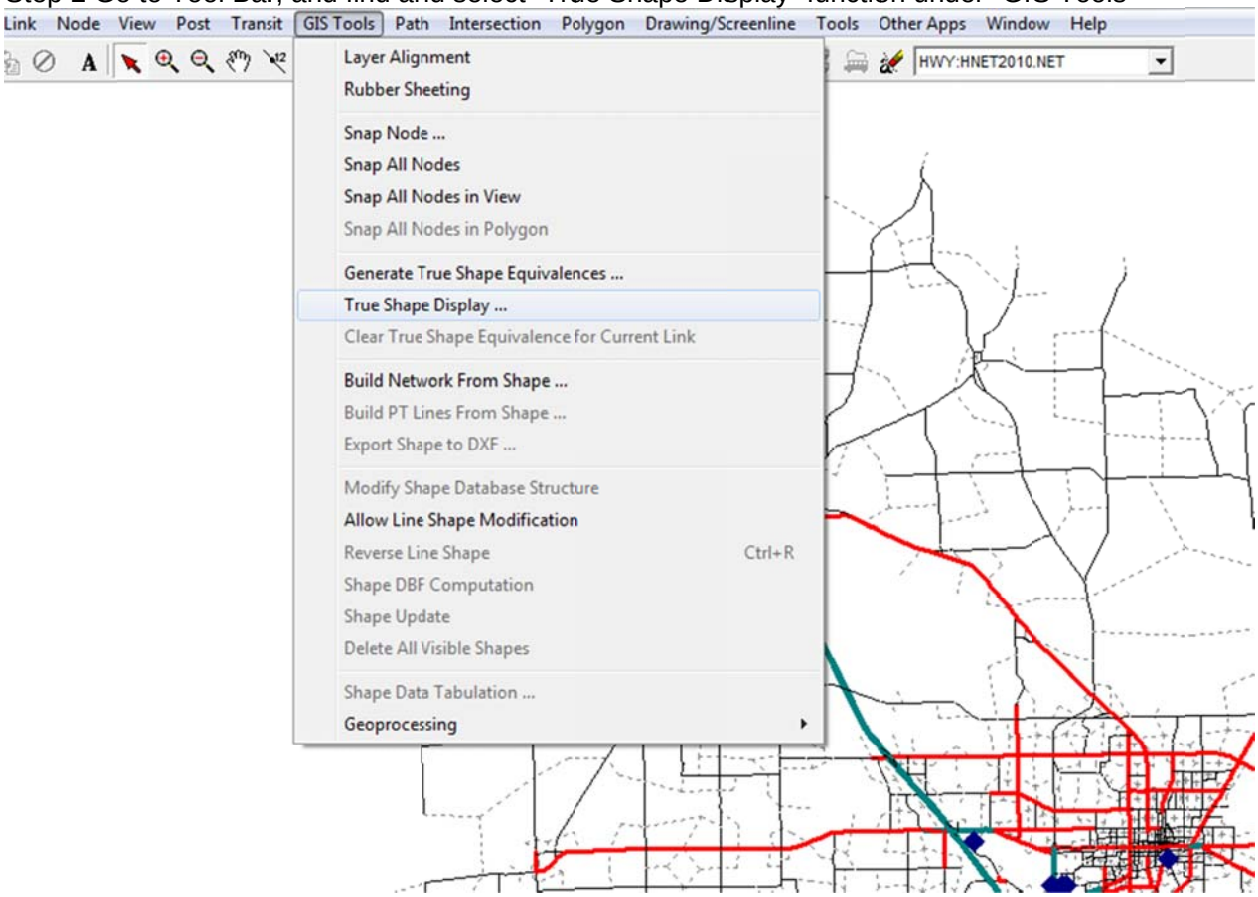
Notes Regarding True Shape Display of Networks

HNET20{YEAR}.NET and COMBINEDLOADED.NET in the Gainesville MTPO 2010 can be shown with True Shapefile Display in Cube software to be shown with curved line shapes. Please use True Shape polyline GIS shapefile which is available in model data in the following file location.
…\Gainesville_2007_2035\Media\Street\HNET2010TrueShp.shp

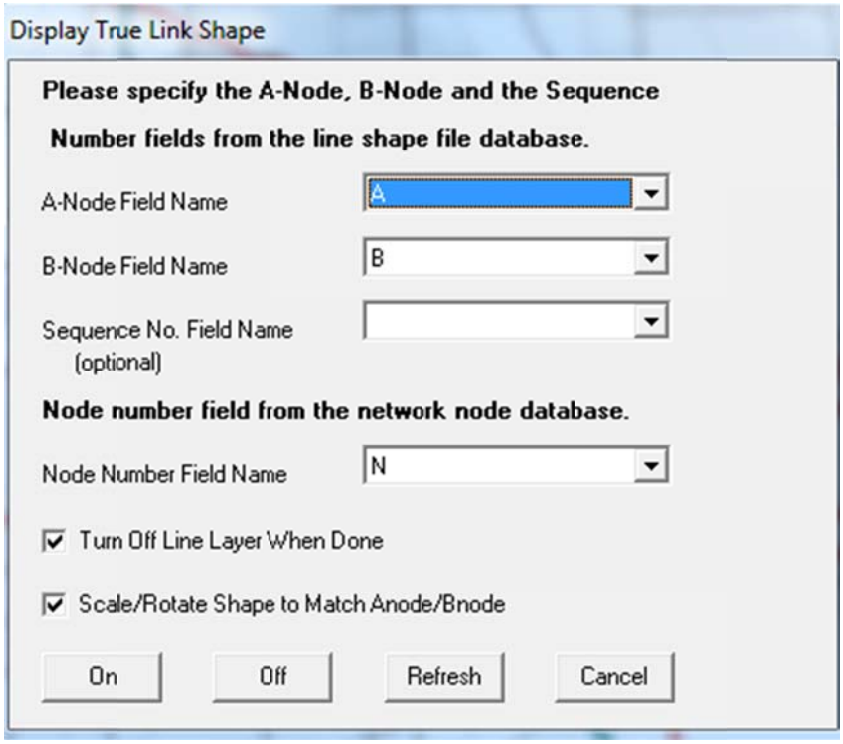
Step 1. Make sure that True Shape GIS shapefile is correctly selected and overlaid underneath the input or output network, as shown in the next screenshot



Step 2 Go to Tool Bar, and find and select “True Shape Display” function under “GIS Tools”



Step 3 “A” should be selected for A-Node, “B” for B-Node and “N” for Node Number. Click Ok.



Now, the network should be displayed with curved shapes instead of straight line shapes.

Appendix F: Glossary and Abbreviations

(Source: FSUTMS CUBE Comprehensive Workshop Front Matter Documentation – April 2010)

Access – Connectivity between a TAZ and the network. Access can be distinguished between highway and transit networks, and between automobile and pedestrian modes.
Advanced Traffic Management Systems (ATMS) -ATMS is the application of information and telecommunications technologies to the management of freeway and surface street facilities to maximize the use of existing roadway capacity, improve safety, reduce congestion, and provide predictable services
Advanced Traveler Information Systems (ATIS) - The collection, aggregation and dissemination of information to assist surface transportation travelers in moving from an origin to a destination.
Advanced Public Transportation Systems (APTS) - The use of information and communication technologies to improve the performance of transit services and level of service provided to customers.
Alightings - The number of persons getting off a transit vehicle.
Area Type - Network link code representing the type of land use in the area.
Attraction - The desirability of a zone. For non-home-based trips, attractions in a zone can be considered synonymous with trip destinations in that zone.
Auto Occupancy Rate - Average number of persons per vehicle.
Best Path - One of many paths between a specific origin and destination pair in a transit network determined to be the most efficient means of traveling from the origin to the destination. The default transit path methodology used in Florida.
Boardings - The number of persons getting on a transit vehicle.
Calibration - A process where models are adjusted to simulate trip-making characteristics of households in the model study area to match observed traffic activity in the study area.
Capacity - The maximum number of vehicles that can pass over a given section of a lane or roadway in one direction (or in both directions for a two-lane or three-lane highway). It is the maximum rate of flow that has a reasonable expectation of occurring. The terms “capacity” and “possible capacity”are synonymous. In the absence of a time modifier, capacity is an hourly volume. In expressing capacity, it is essential to state the prevailing roadway and traffic conditions under which the capacity is applicable. The capacity would not normally be exceeded without changing one or more of the conditions that prevail.
Centroid - Centroids are nodes used to identify the center of activity within a traffic analysis zone.
Centroid Connector - The Centroid Connector connects the traffic analysis zone centroid to the surrounding network links.
Cordon Line - An imaginary line encircling a study area. Traffic counts, travel origins and destinations, and other traffic data are collected at the locations where the imaginary line intersects the roads entering and leaving the study area. Used in modeling to estimate traffic entering and exiting the study area.
Commercial Vehicle Operations (CVO) - ITS technologies that uniquely support commercial vehicle operations to promote safe, economical, and efficient truck transportation.
Cube Voyager - A modeling software, developed by Citilabs, used as a modeling engine for the Florida Standard Model.
Demand - A desire for travel from an origin to a destination. Demand is not a fixed amount of travel, but a function of level of service.

Destination - Location to which trips are made, variously identified as a zone of specified area (in aggregate travel forecasting) or a location with a specified "attraction power," measured by things such as employees (for work trips) or square feet of sales area (for shopping trips).
Desire Line - Lines on a map representing the number of trips between zones. The thicker the line, the larger the number of trips.
EE Trips - External-External trips represent trips that travel through but have both trip ends outside of the model study area.
Facility Type - A network link code representing the type of service a roadway provides, such as principal arterial, minor arterial, collector, etc. The facility type does not always match the functional classification, as the facility type is used for modeling purposes only to simulate actual conditions.
Friction Factors (F-Factors, FF) - Reflects the regional sensitivities toward certain trip lengths for certain trip purposes. For example, home-based shopping trips may tend to be shorter than home-based work trips. Used to modify impedance during trip distribution.
Gravity Model - A mathematical model of trip distribution based on the premise that trips produced in any given area will distribute themselves in accordance with the accessibility of other areas and the opportunities they offer.
Headway - The amount of wait time between arrivals at a given transit stop for a given transit line.
Highway-Only Model - A model that only includes a roadway network thereby excluding transit.
Home-Based Trip - A trip with one end at the residence of the person making the trip.
HOV Trips - High Occupancy Vehicle trips, or carpool trips, represent the number of trips with usually two or more persons in the vehicle, including the driver.
Impedance - More general than Friction Factors, impedance shows the effect that various levels of time and cost will have on travel between zones. Impedance can include various types of time (walking, waiting, riding, etc.) and cost (fares, operating costs, tolls, parking costs, etc.). Other factors, such as comfort, convenience, personal safety, etc., may also be included.
IE Trips - Internal-External trips represent trips that have one end inside the model study area and one end outside the model study area.
II Trips - Internal-Internal trips represent trips that have both ends inside the model study area.
Incident Management Systems - These systems manage both predicted and unexpected incidents so that the impact to the transportation network and traveler safety is minimized. Incident management involves five major phases. These are incident detection, incident verification, incident response, incident clearance, and queue dissipation.
Intelligent Transportation Systems (ITS) - The application of information and telecommunications technologies to the management and operation of transportation systems.
IntelliDrive/Vehicle-Infrastructure Integration (VII) - The establishment of vehicle to vehicle and vehicle to roadside communication capability nationwide to enable a number of new services that provides significant safety, mobility, and commercial benefits.
Intrazonal Trip - A trip with both its origin and destination in the same zone.
Kiss-and-Ride (KNR) - A type of transit trip characterized by a transit rider being dropped off at a transit station by automobile and boarding a transit line.
Level of Service (LOS) - Multidimensional characteristics of the transportation service provided that are usually identified specifically by the location of the origin and destination of a trip and that are divided into those that are quantifiable (travel time, travel cost, number of transfers) and those that are difficult to quantify (comfort, mode image).
Link - A basic component of a network representing a segment of roadway. This component is a primary unit of analysis and carries data pertaining to roadway characteristics, traffic volumes, and performance measures.

Managed Lanes - Managed lanes help maximize the use of existing highway capacity by using price and/or occupancy restrictions to manage the number of vehicles traveling on them. Managed lanes maintain volumes consistent with acceptable levels of service even during peak travel periods.
Micro-coding - A transit modeling technique used to introduce a higher level of detail at transit stations by separating access points between modes and introducing links connecting them. Allows a more realistic representation of transferring between modes.
Mode Choice - Mode choice models calculate which trips will use the highway network and which will use the transit network. The model predicts how the trips will be divided among variable modes of travel.
Mode of Travel - Means of travel such as auto driver, vehicle passenger, mass transit passenger, walking or bicycle.
Nested Logit Model (NLM) - Analytical form for demand modeling that is suited to modeling of multiple travel choice situations by grouping different modes of travel according to their likelihood for direct competition.
Network - Set of nodes and connecting links that represent transportation facilities in an area. Attributes normally associated with links are distances, levels of service, capacities, and volumes.
Node - A point where two links join in a network, usually representing a decision point for route choice but sometimes indicating only a change in some important link attribute.
Occupancy Model - Converts person trips to vehicle trips using auto occupancy factors.
Origin - The location of the beginning of a trip or the zone in which a trip begins.
Park-and-Ride (PNR) - A type of transit trip characterized by the act of parking at a transit station and boarding a transit line.
Path - A set of links representing a possible route between an origin and a destination. There can be a number of paths between any specific origin and destination pair.
Peak Period - The period during which the maximum amount of travel occurs. This may be one or more hours. Generally, there is a morning peak and an afternoon peak and traffic assignments may be made for each period.
Productions - The number of home-based trip ends in the zone of residence. For all non-home based trips, productions are synonymous with origins.
Ramp Metering - The application of signal control devices to regulate the number of and/or how vehicles merge into the freeway mainline lanes with the objective in most cases to balance flow and demand.
Ridership - Number of individuals using a transit line. Used as an assessment of a transit line's attractiveness.
RMSE - Root Mean Square Error is a measure of total error defined as the square root of the sum of the variance and the square of the bias. It assumes that larger forecast errors are of greater importance than smaller ones; hence they are given a more than proportionate penalty.
Road-Weather Information Systems (RWIS) - RWIS provides information to travelers and also to agencies for better deployment of resources. They use combinations of weather information services and data collected from environmental sensors.
Screenline - An imaginary line, usually along a physical barrier such as a river or railroad tracks, splitting the study area into parts. Traffic counts and possibly interviews are conducted along this line, and the crossings are compared to those calculated from the home interview data as a check of survey accuracy. Crossing may also be compared with model estimates as part of calibration.
Selected Link Analysis - Traces the entire length of each trip passing through a particular link or set of links along the network to determine where such trips are coming from and going to.
Selected Zone Analysis - Traces the entire length of each trip traveling to or from a particular zone or set of zones.

Shortest Path - A path representing the least cost option of traveling between any specific origin and destination pair.
Signal Preemption - Traffic signal preemption is a type of system that allows the normal operation of traffic lights to be preempted, often to assist emergency vehicles. The most common use of these systems is to provide emergency vehicles priority by changing traffic signals in the path of the vehicle to green and stopping conflicting traffic.
Smart work zones (SWZ) - SWZ are automated systems that provide real-time information on work zone traffic conditions. In recent years, transportation agencies across the nation have deployed portable ITS technologies to monitor traffic and manage mobility and safety during construction and maintenance of highways.
Socioeconomic Data - Demographic data, such as household, population, and employment characteristics, that are input into the model to determine the impact on trip-making patterns.
SOV Trips - Single Occupancy Vehicle trips, or drive-alone trips, represent the number of trips with only one person in the vehicle, including the driver.
Special Generators - Concentrations of activities of such size or unusual nature to warrant special consideration in trip generation analysis.
Station - A node in the transit network that offers an opportunity for automobile access. FSUTMS
Stop Node - A node along a transit line that represents an opportunity for boardings and alightings.
Study Area Boundary - The area that is expected to take on urban characteristics in the next 20 to 30 years (by the end of the planning period).
TAZ - Traffic Analysis Zone - a small geographic area that serves as the primary unit of analysis in a travel forecasting model.
Traffic Count - The observed number of trips collected at a specific location. Used to assist with model validation.
Transit Legs - Distinct units of a transit line representing a segment from one stop to the next. Transit paths are built by assessing the relative costs of available transit legs.
Transit Line - A collection of transit stops arranged into a route along which public transport vehicles travel. A system of interacting transit lines is a transit network
Transit Signal Priority - Transit Signal Priority (TSP) is an operational strategy that facilitates the movement of in-service transit vehicles through traffic signal controlled intersections. Signal priority modifies the normal signal operation process to better accommodate transit vehicles.
Transportation Model - A mathematical description of a transportation system's characteristics including traffic volumes, and use, roadway type and population. After a mathematical relationship is established, the model is used to predict traffic volumes based on anticipated changes in the other characteristics.
Trip Assignment - The process of determining route or routes of travel and allocating the zoneto-zone trips to these routes.
Trip Distribution - The process by which the movement of trips between zones is estimated. The data for each distribution may be measured or estimated by a growth factor process, or by synthetic model.
Trip End - Either a trip origin or a trip destination.
Trip Generation - A general term describing the analysis and application of the relationships that exist among the trip makers, the urban area, and trip making. It is used to determine the number of trip ends in any part of the urban area.
Trip Purpose - The reason for making a trip, normally one of several possible purposes. Each trip may have a purpose at each end; (e.g., home to work) or may be classified by the purpose at the non-home end (e.g. home to shop).
Trip Table - A table showing trips between zones -- either directionally or total two-way. The

trips may be separated by mode, by purpose, by time period, by vehicle type, or other classification.
Trip Rate - The average number of trips per household for specific trip purposes. In Florida, trip rates are usually applied by household size and auto availability within each zone by trip purpose.
Validation - The procedure used to adjust models to simulate base year traffic conditions. A preliminary step that must be undertaken before models may be reasonably used to forecast future traffic conditions.
VHT - Vehicle hours of travel.
VMT - Vehicle miles of travel.
Volume-to-Capacity Ratio - The number of trips simulated in the model divided by the capacity of the link. A volume-to-capacity ratio of 1.0 represents 100 percent of the capacity.
Volume-to-Count Ratio - The number of trips simulated in the model divided by the count on the link. A volume-to-count ratio of 1.0 represents an exact match between the simulated volumes and the observed counts. Typically assessed only during validation.

ACRONYMS (Sourced from FDOT Project Forecasting Handbook 2002)
ADT Average Daily Traffic
AADT Annual Average Daily Traffic
D Directional traffic split
D30 Proportion of traffic in the peak direction for the 30th highest hour
DHV Design Hour Volume
DDHV Directional Design Hour Volume
DHT Design Hour Truck Percentage
ESAL Equivalent Single Axle Load

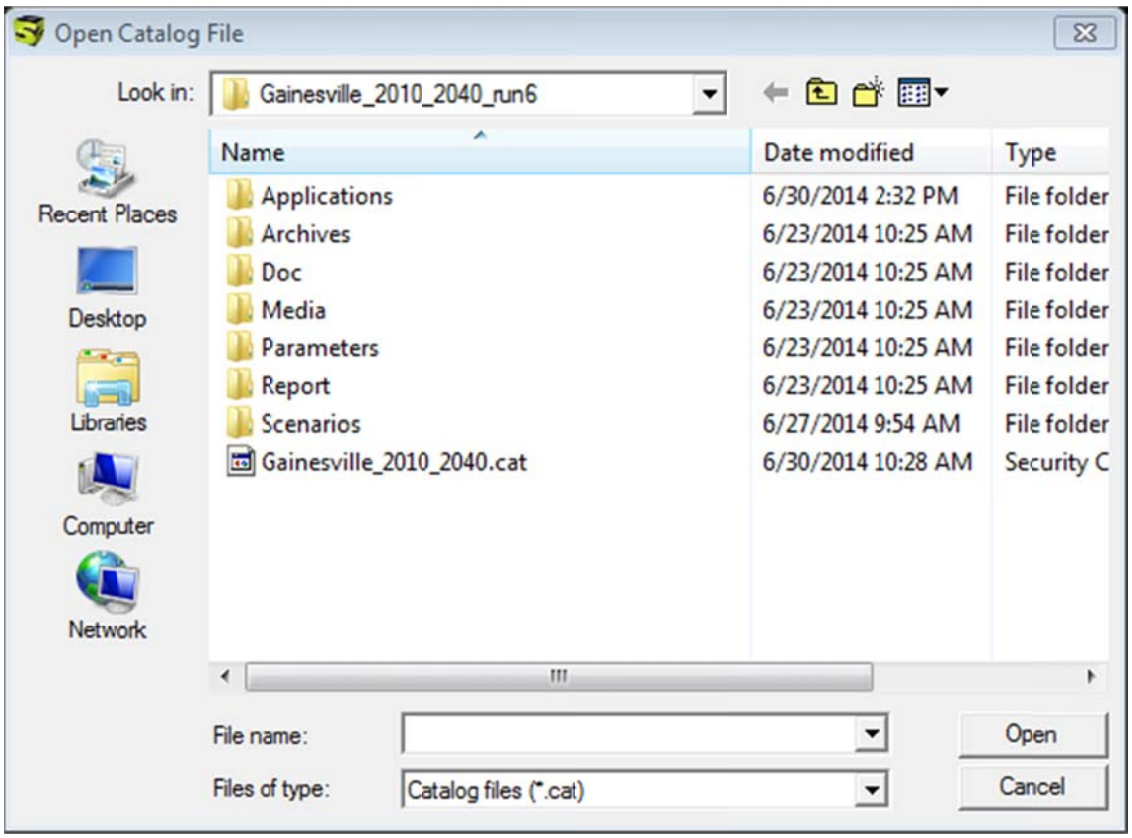
Appendix G: Scenario Manager / Running the Model

1. To run the Alachua County model, you first have to open up the Cube Application window by navigating to it or clicking the Cube desktop icon

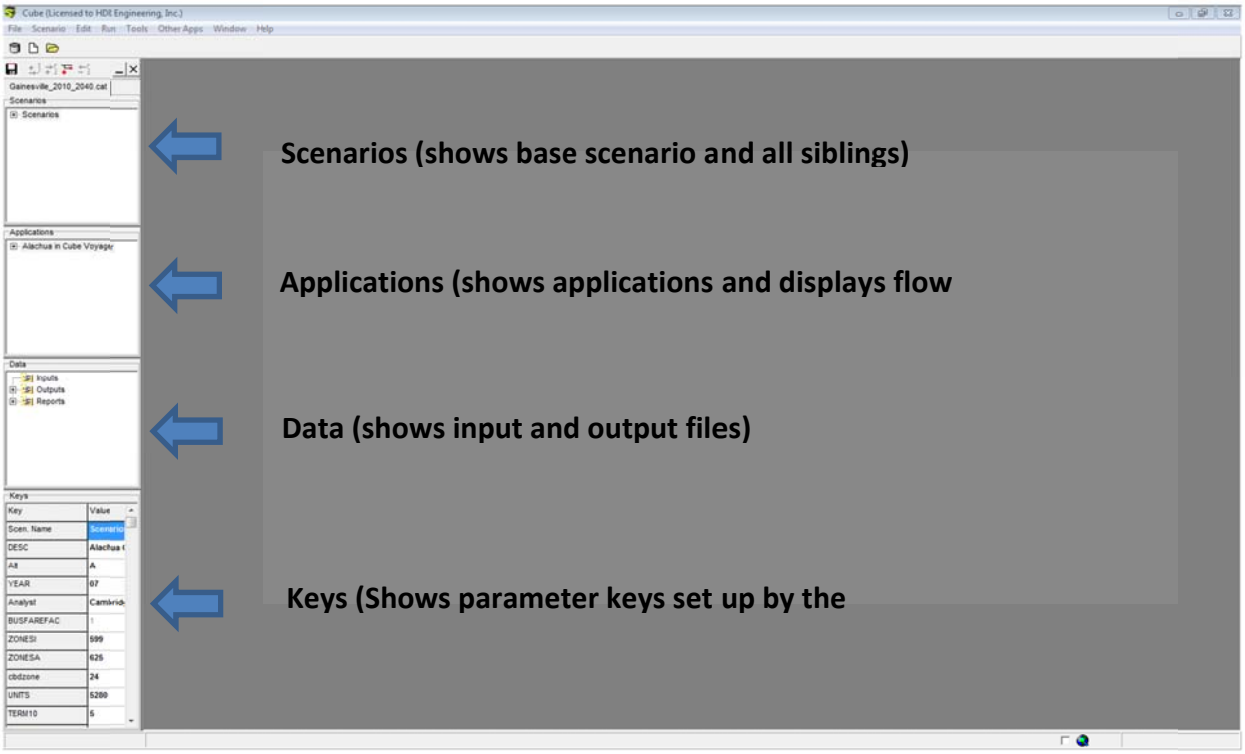
2. This brings up a dialog asking for the catalog location of the model.

3. Navigate to the location for the catalog on your computer/network and open it.

The second way to open the model is to double click Gainesville_2010_2040.cat in Windows Explorer.

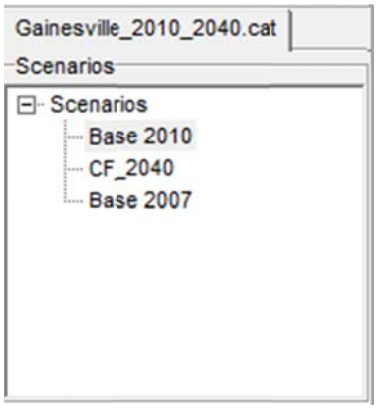


4. This brings up the Gainesville model application window.

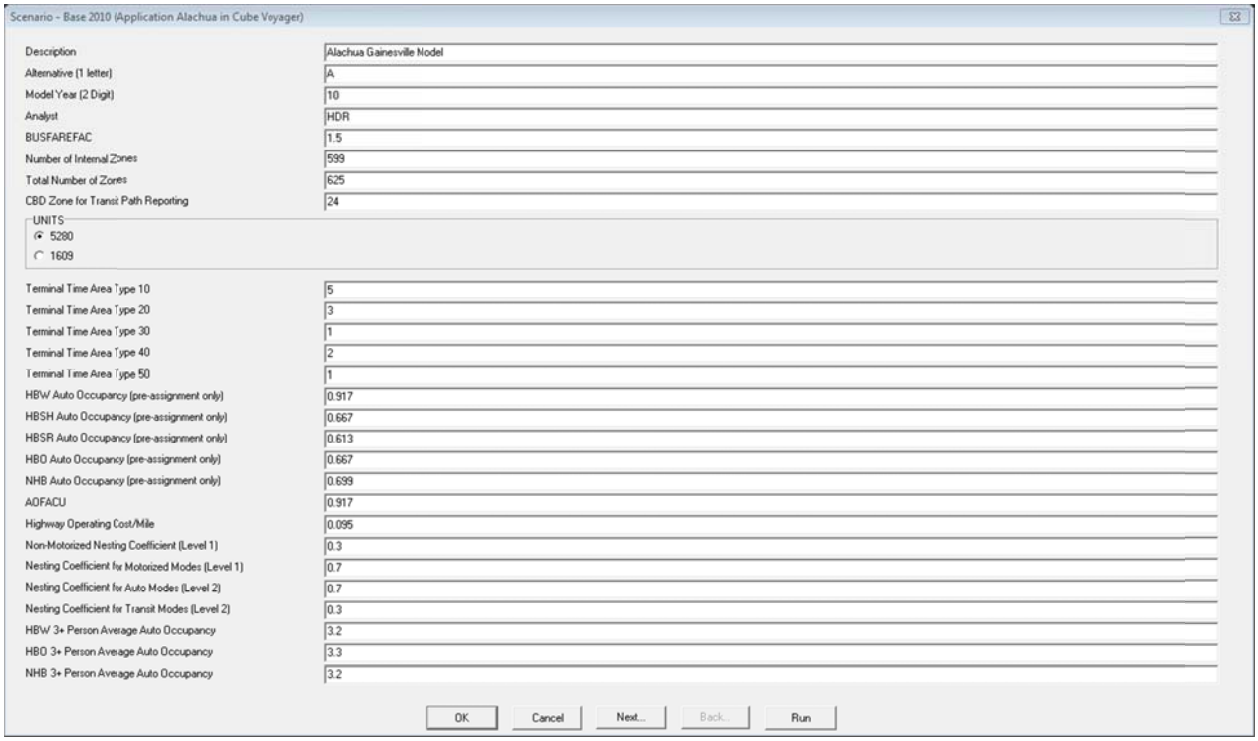


The figure above shows the various parts of the Cube catalog application window.

5. To run a particular scenario, for example the Base Year**,** you would select **Base 2010 in the Scenarios section of the catalog.**



When a scenario is double-clicked, the Scenario dialog box is displayed as illustrated below.



This dialog box allows you to change model runtime options and set model parameters. These parameters are stored as Cube Catalog Keys which are variables which are referenced in the model script during the relevant model processing phase. The Catalog Key values can also be observed in Part 4 of the Catalog File diagram above.

6. To run the model with the indicated variables, simply press **Run** and then **OK** and the model will be launched. When the model run is completed, press **OK.** You may then analyze the results. The **Applications** section of the Catalog file shows the model processes and may be used to open the Cube Application Flowchart for a specific step or for the overall model.

The **Data** section of the Catalog file shows the input files, output files and any reports generated by the model run processes.

For further details on the Scenario Manager and running FSUTMS models, you may refer to the FSUTMS Comprehensive Modeling Workshops held periodically throughout the year in various locations across the state.
